

SHIPS, WAVES AND MATH

Mathematics & Water, Deltares, 13 November 2014

MARIN, Ed van Daalen

CONTENTS

- MARIN
- Application of math to ship hydromechanics
- Conclusions

MARITIME RESEARCH INSTITUTE NETHERLANDS

- hydrodynamic research for maritime industry, nonprofit
- founded 1929, 7 model basins, 350 employees, 42 M€ turnover
- model tests, trials & full scale monitoring, simulations
- international market: design companies, shipyards, classification, ship operators

- Ships: powering & resistance, seakeeping, manoeuvring for all ship types
- Offshore: on/offloading, drilling platforms, windmill installation
- Nautical Simulator: harbour design, training
- Trials and Monitoring: full scale measurements
- Software: simulation
- Production: model factory, instrumentation
- Research and Development: fundamental developments in experiments and simulations

Record number of visitors at open day

Last Saturday November 8 a record number of 5500 visitors were introduced to the world of model testing and hydrodynamics during the MARIN open day.

Throughout the day interactive demonstrations were given at the testing facilities in Wageningen. Most basins were open to visitors, who got a chance to see live model tests taking place. They could even ride on a towing carriage and experience a real model test firsthand! On the route visitors could see how ship models and propellers are manufactured and they could even join the Captain on the simulator bridge.

MARIN present at 23rd HISWA Symposium, November 17 & 18, Amsterdam

MARIN will be presenting a paper on "Early design estimation of resistance and seakeeping properties based on systematic model experiments" at the 23rd edition of the International HISWA Symposium. MARIN is also co-sponsor of the event.

Differences in workload of both skippers and pilots due to changes in environmental bank lights

The effect of changes in environmental bank lights (pudde lights) on both inland skippers and pilots is studied in a manoeuvring simulator using physiological workload measurements. Event analysis is based on a combination of analytical indicators (distance between vessels) and cognitive...

THRUST ALLOCATION

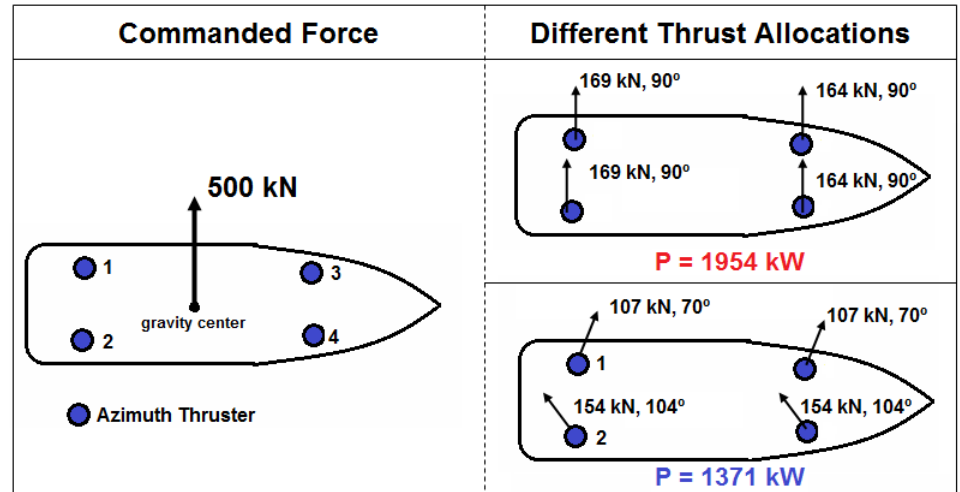

THRUST ALLOCATION - OBJECTIVES

Dynamic Positioning (DP) System

Thrust Allocation Algorithm

- match required forces
- minimize power
- account for hydrodynamic interaction effects
- respect physical limitations
 - maximum rpm change
 - maximum azimuth change

THRUST ALLOCATION – INTERACTION EFFECTS

thruster-hull interaction

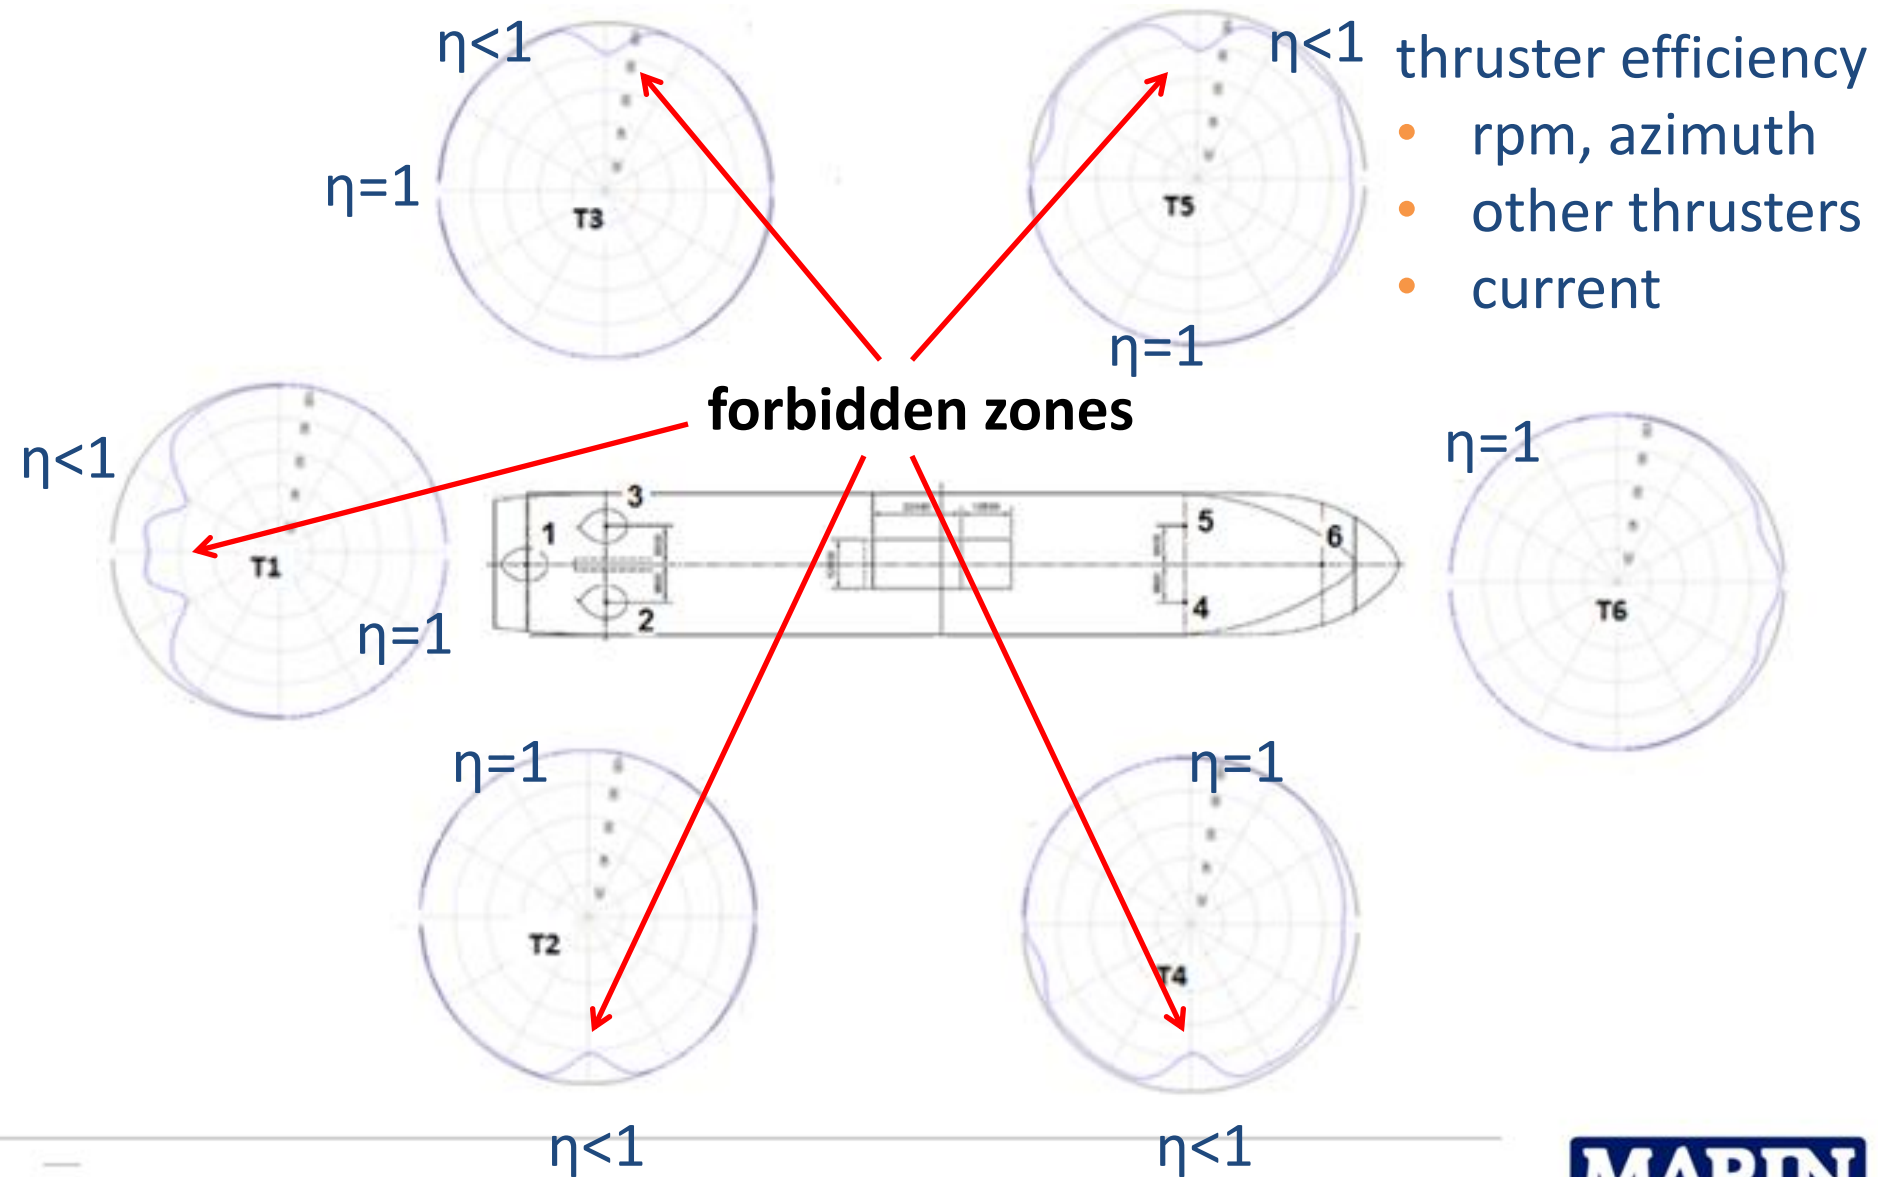

thruster-current interaction

thruster-thruster interaction

THRUST ALLOCATION - EFFICIENCY FUNCTIONS

THRUST ALLOCATION - OPTIMIZATION PROBLEM

$$\text{Min}_{T, \alpha} \sum_{i=1}^N c_i(\rho, D) \cdot \frac{C_{Q_i}}{C_{Q_{0_i}}} \cdot T_i^{\frac{3}{2}}$$

power minimization

$$R: \left\{ \begin{array}{l} \sum_{i=1}^N T_i \cdot \cos \alpha_i \cdot \eta_i - F_x = 0 \\ \sum_{i=1}^N T_i \cdot \sin \alpha_i \cdot \eta_i - F_y = 0 \\ \sum_{i=1}^N [T_i \cdot \eta_i \cdot (x_i \cdot \sin \alpha_i - y_i \cdot \cos \alpha_i)] - M_z = 0 \end{array} \right.$$

generate required forces

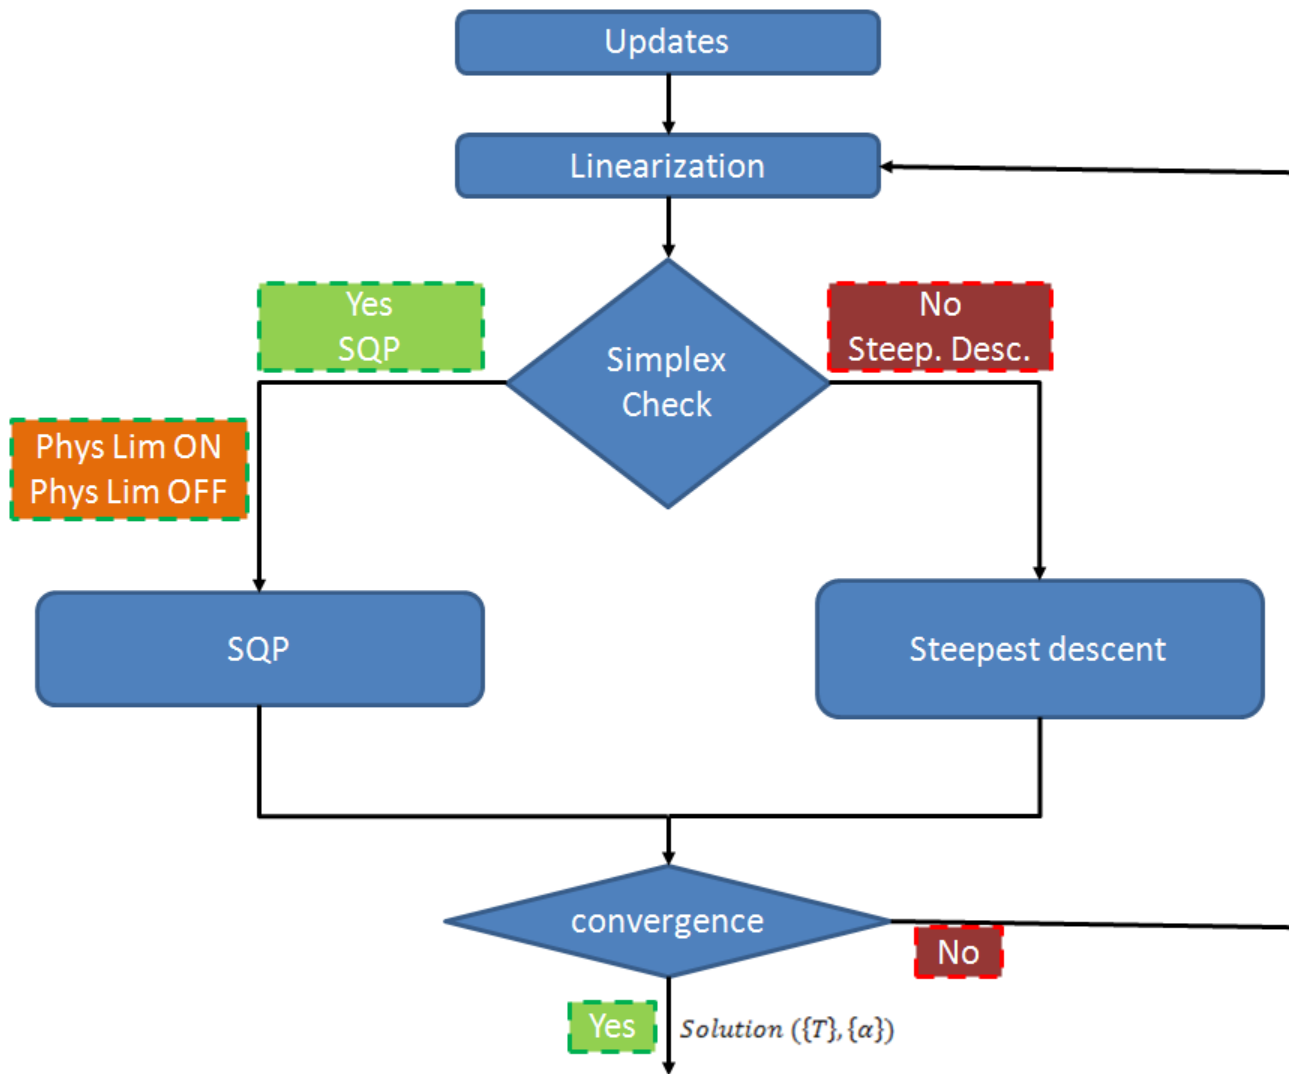

account for hydrodynamic interactions

$$I: \left\{ \begin{array}{l} T \leq T_{max} \\ \Delta \alpha \leq \Delta \alpha_{max} \\ Lb \leq T \leq Ub \end{array} \right.$$

physical limitations

THRUST ALLOCATION - ALGORITHM

THRUST ALLOCATION - CROSSING FORBIDDEN ZONES

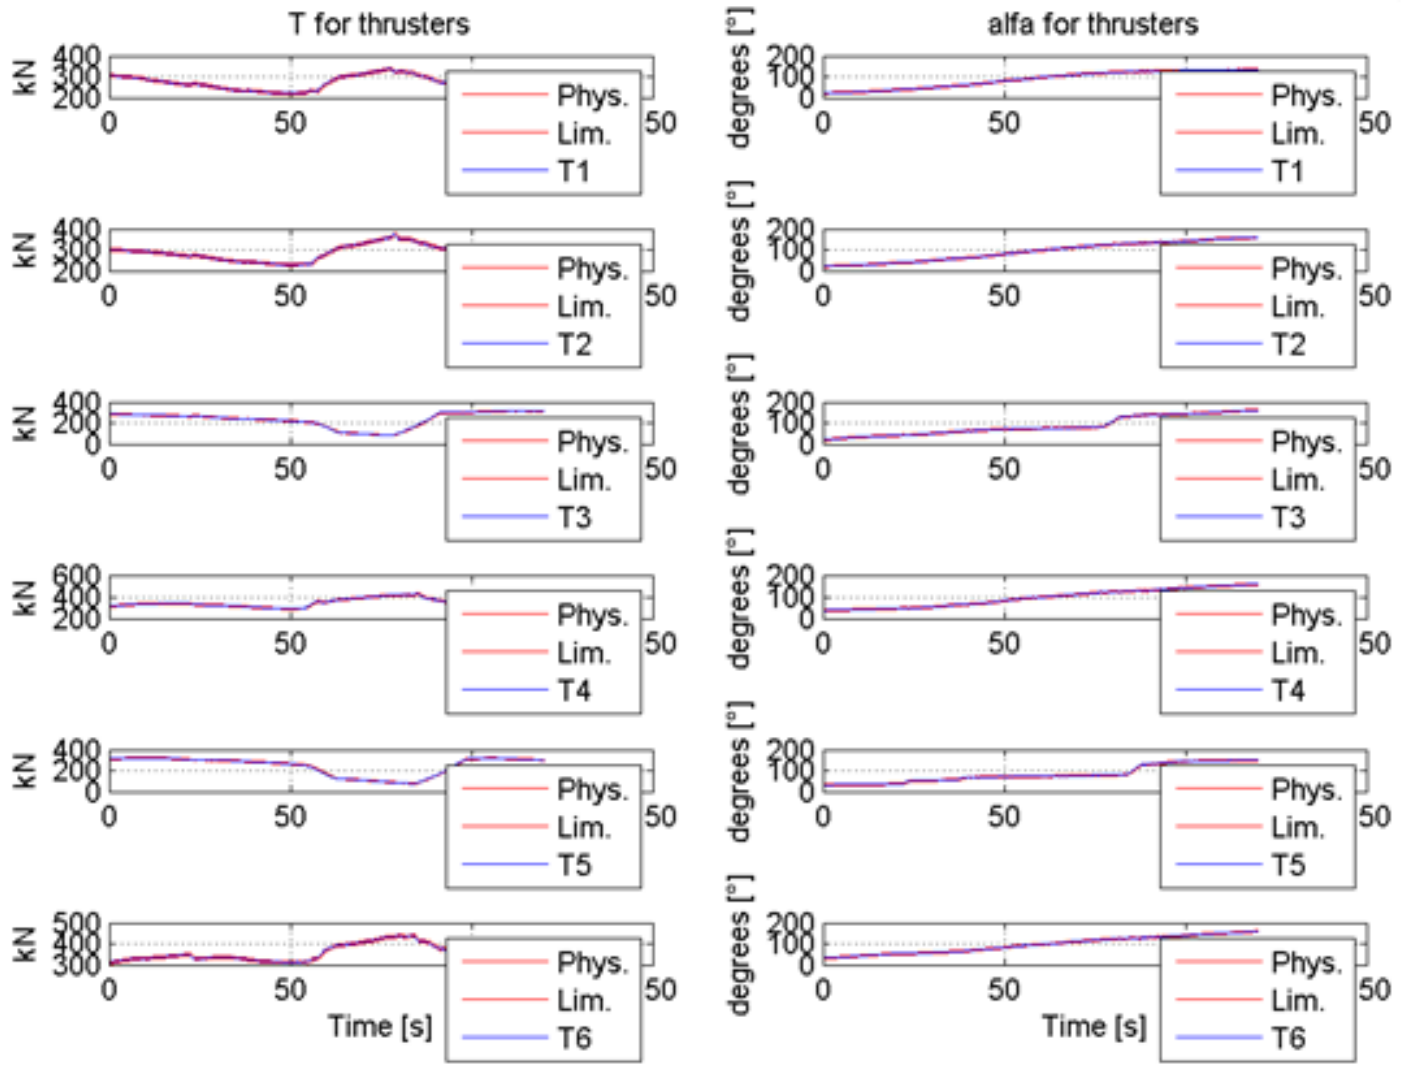

Casus 1 (60%), 6 thrusters configuration, saturation, limited azimuth ratio, limited rpm ratio, fail in T6, time 0 s

THRUST ALLOCATION – MATCH REQUIREMENTS

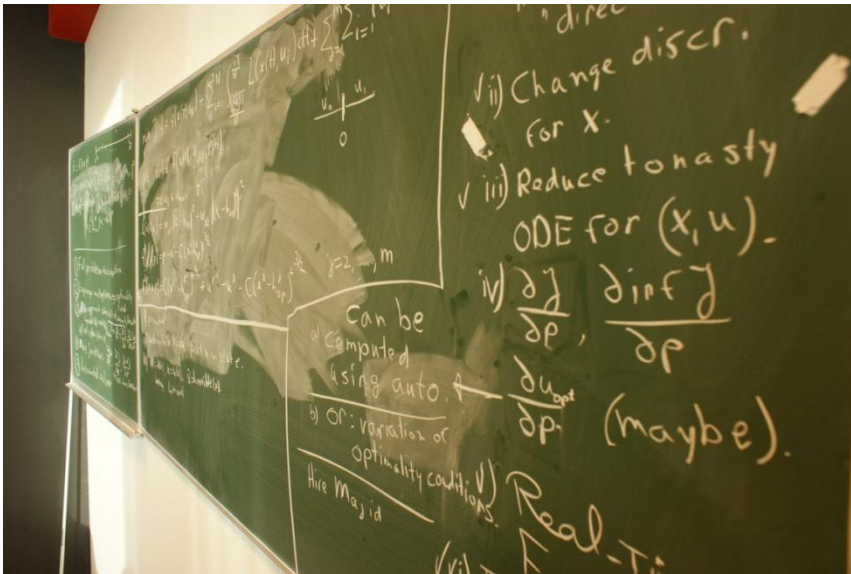

THRUST ALLOCATION – RESPECT PHYSICAL LIMITS

MANOEUVERING EQUATIONS

research started at SWI 2011

- maneuvering model: set of coupled ordinary differential equations (ODEs) describing *ship motions in calm water*, including nonlinear hull forces and nonlinear propulsion forces
- many hull parameters (~ 30) and propulsion parameters (~ 20) involved
- many of these parameters are determined by experiments (scale models) and CFD

MANOEUVERING EQUATIONS – MATHEMATICAL MODEL

- Propeller-Rudder Model: used in MARIN maneuvering simulation program SURSIM

$$\begin{aligned}
 L_{pp}((m'+m'_{uu})\dot{u}) &= m' r' v + X'_H + X'_R + X'_P \\
 L_{pp}((m'+m'_{vv})\dot{v} + m'_{vr} \dot{r}') &= -m' r' u + Y'_H + Y'_R \\
 L_{pp}(m'_{rv} \dot{v} + (I'_{zz} + m'_{rr})\dot{r}') &= +N'_H + N'_R
 \end{aligned}$$

- (simplified) Thruster Model:

$$\begin{aligned}
 L_{pp}((m'+m'_{uu})\dot{u}) &= m' r' v + X'_H + \tau \cos \alpha \\
 L_{pp}((m'+m'_{vv})\dot{v} + m'_{vr} \dot{r}') &= -m' r' u + Y'_H + \tau \sin \alpha \\
 L_{pp}(m'_{rv} \dot{v} + (I'_{zz} + m'_{rr})\dot{r}') &= +N'_H + x'_T \tau \sin \alpha
 \end{aligned}$$

$$\rightarrow \underline{\dot{u}} = \underline{F}(\underline{u}, \underline{\lambda})$$

$$\underline{\dot{u}} = \underline{F}(\underline{u}, \underline{\lambda})$$

obvious thing to do = direct simulation

→ time integration with initial conditions

- constant propulsion parameters: e.g. straight line, turning circle
 - NOTE for these motions $\underline{\dot{u}} = \underline{0}$
- time-dependent propulsion parameters: e.g. zig-zag manoeuver
 - NOTE for these periodic motions $\underline{\dot{u}} \neq \underline{0}$

Alternative: Numerical Continuation Method

NCM = a robust and fast method to

- find parameter-dependent set of 'equilibria' of ODEs (equilibrium = steady / stationary state solution)
- determine stability properties of equilibria
- find bifurcations and e.g. trace periodic solutions (bifurcation = transition from stable to unstable)

MANOEUVERING EQS - NUMERICAL CONTINUATION

NCM is based on Implicit Function Theorem, stating that
« relations can be transformed into functions »

$$\underline{\dot{u}} = \underline{F}(\underline{u}, \underline{\lambda}) \rightarrow \underline{0} = \underline{F}(\underline{u}, \underline{\lambda})$$

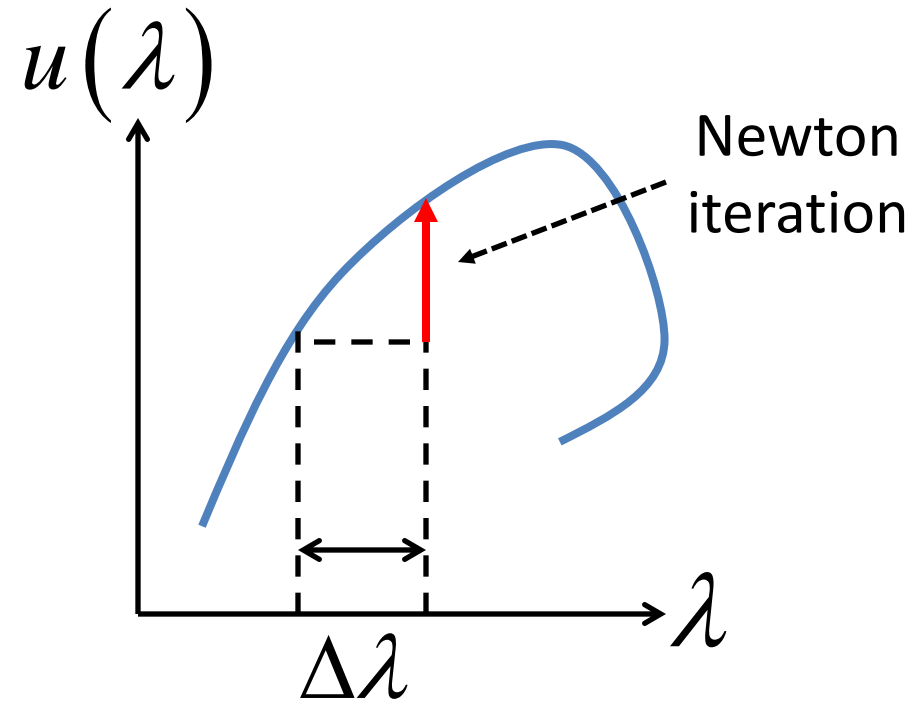

\underline{u} : n-vector (state variables, n=3, 4)
 $\underline{\lambda}$: continuation parameters (select 1)

MANOEUVERING EQUATIONS - NCM WITH AUTO

pseudo arc-length
continuation (AUTO)

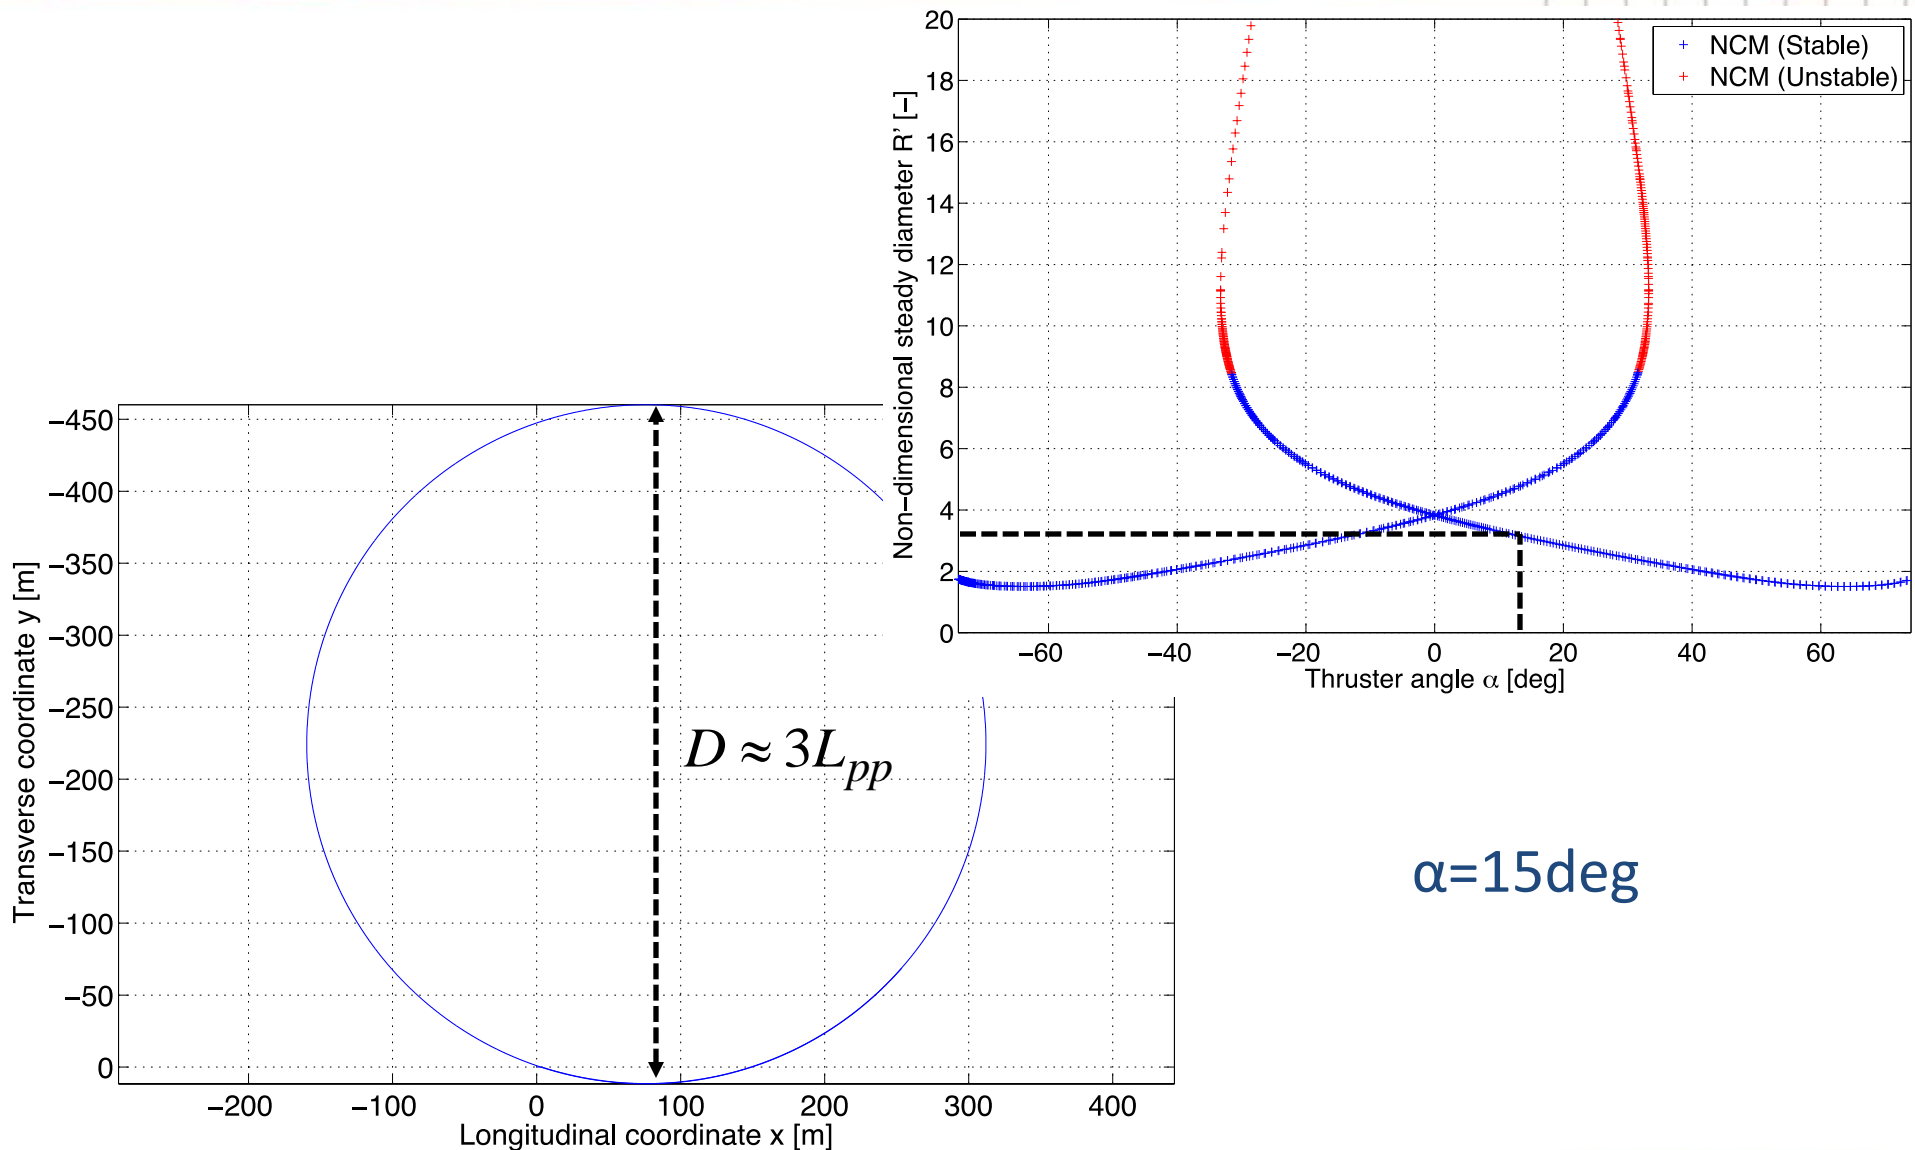

natural parameter
continuation

MANOEUVERING EQUATIONS - TURNING CIRCLE

MANOEUVERING EQUATIONS - TURNING CIRCLE

$\alpha=15$ deg

MANOEUVERING EQUATIONS - STRAIGHT LINE

MANOEUVERING EQUATIONS - YAW CONTROL

add yaw as state variable

$$\underline{u} = (u, v, r', \psi)$$

add extra ODE:

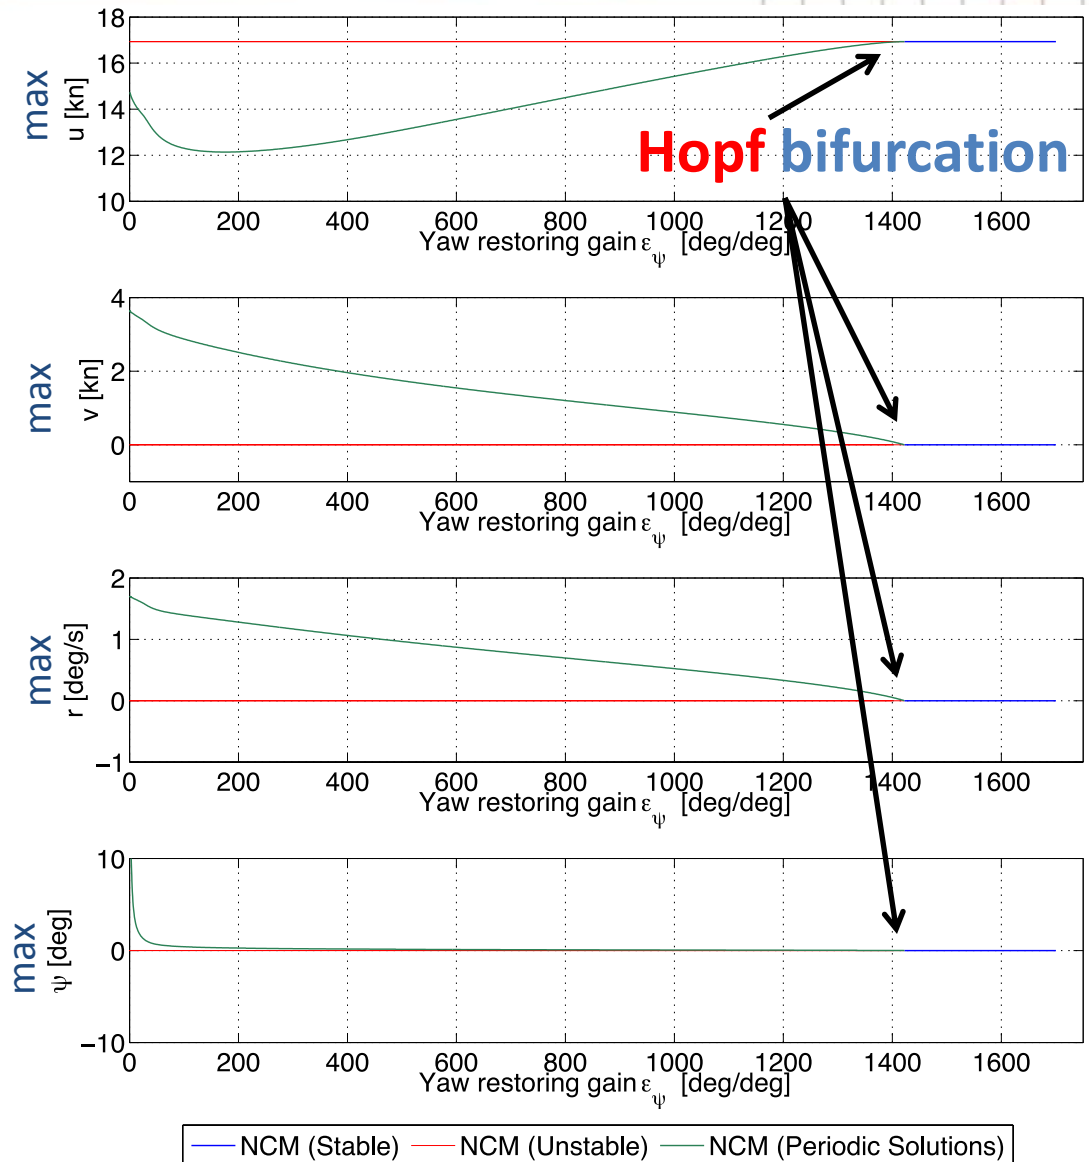

$$\dot{\psi} = r$$

add yaw restoring control:

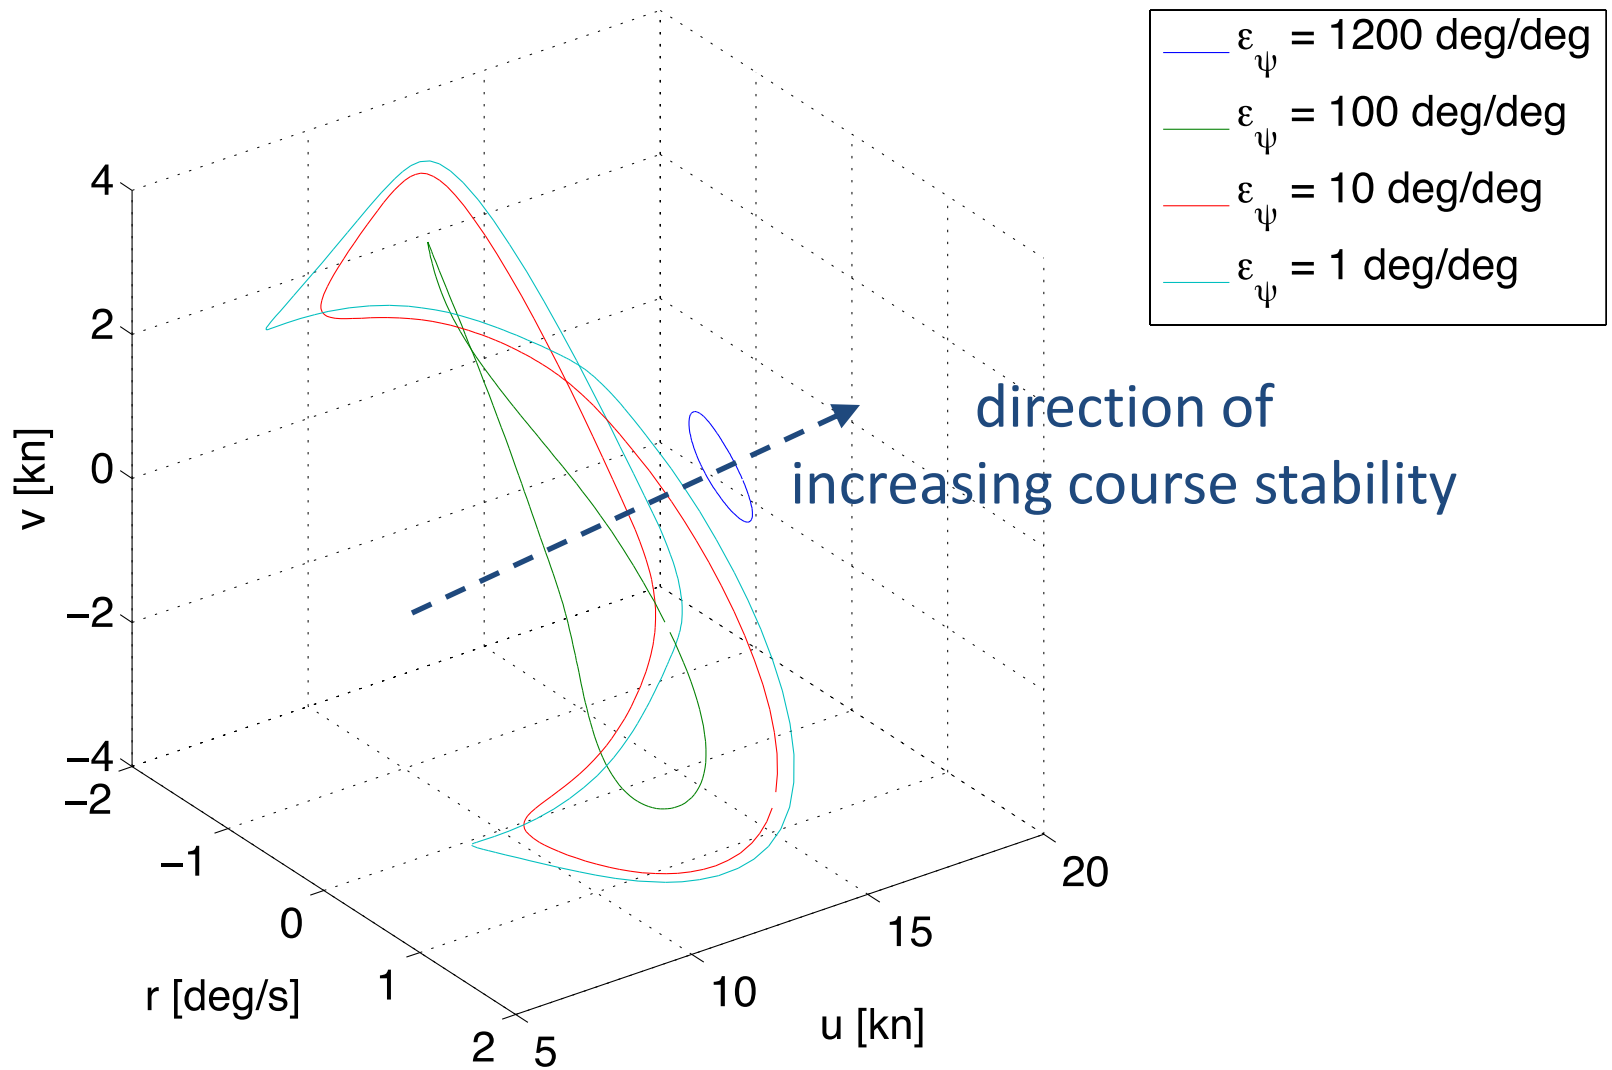

$$\alpha = \alpha_0 + \varepsilon_{\psi} (\psi - \psi_0)$$

$$\alpha_0 = 0$$

(α is a parameter,
not a state variable!)

MANOEUVERING EQUATIONS - YAW CONTROL

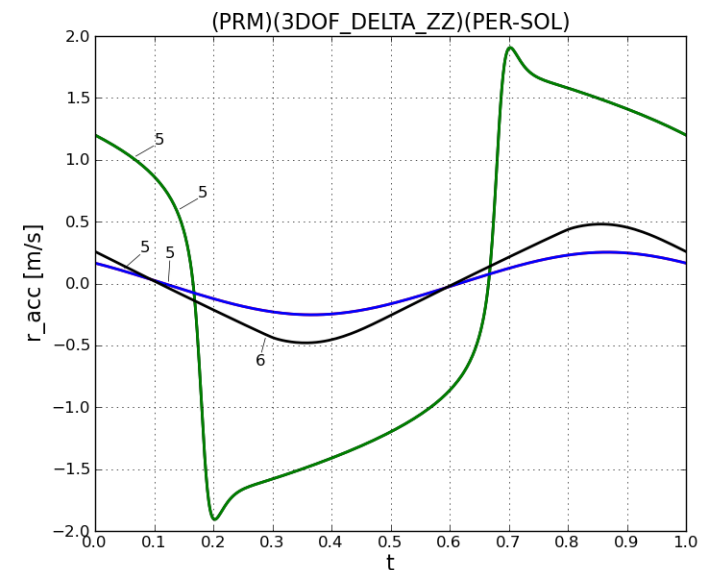

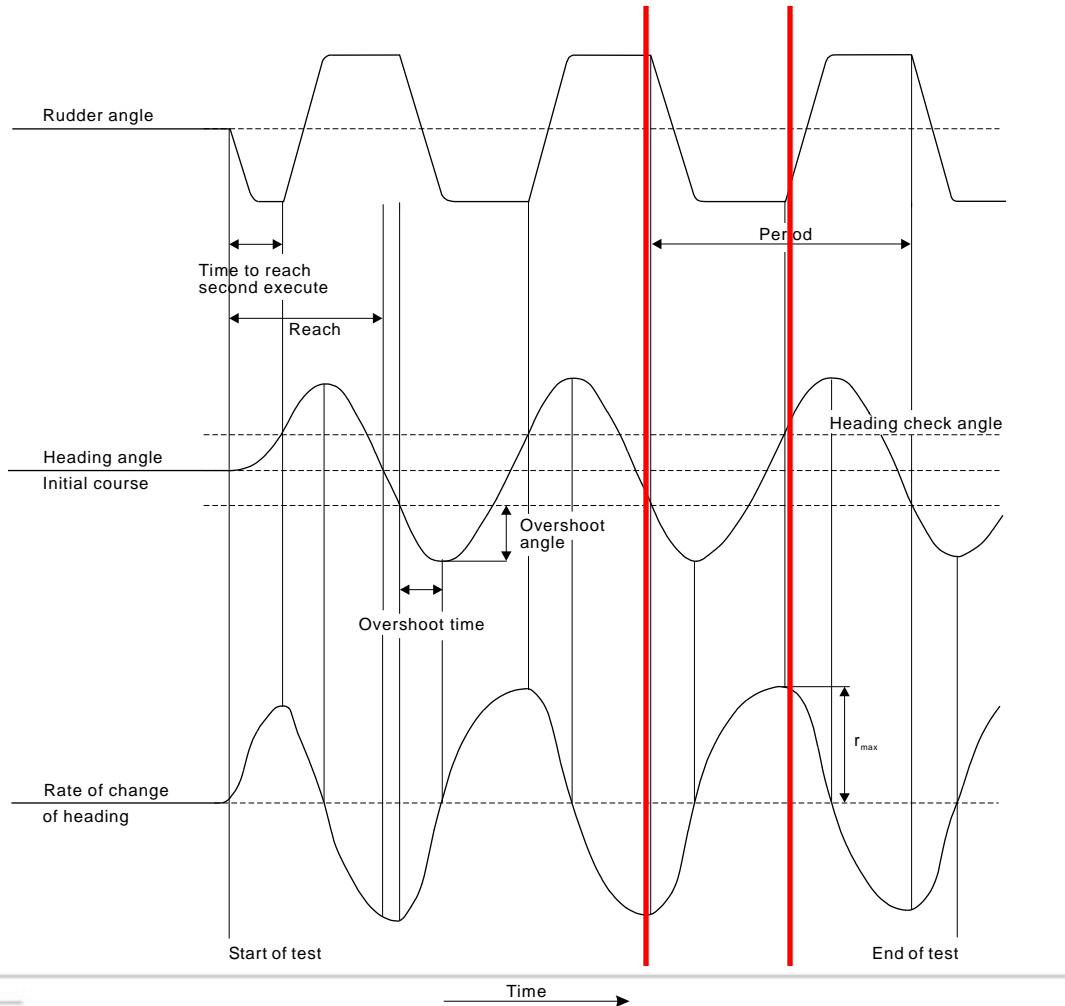

MANOEUVERING EQUATIONS - YAW CONTROL

MANOEUVERING EQUATIONS - ZIGZAG

consider half zigzag only and use anti-symmetric boundary conditions

PARAMETRIC ROLLING

What happens if a container ship experiences large roll angles ?

PARAMETRIC ROLLING - SIMPLE ODE MODEL

simulation over large time intervals

$$(I + A)\ddot{\phi} + B(\dot{\phi})\dot{\phi} + C(t)\phi = 0 \quad C(t) = \rho g V (GM + \partial GM(t))$$

waves

wave force

$$h(t) = \sum_{j=1}^n h_j(t) = \sum_{j=1}^n \sqrt{2d(a,b)} \cos(\omega_j t + \gamma_j),$$

$$\partial GM(t) = \sum_{j=0}^n A_j \sqrt{2d(a,b)} \cos(\omega_j t + \gamma_j + \beta_j)$$

transfer coefficients for amplitude change and phase shift

of waves acting upon metacentric height: $A_j = A(\omega_j)$ $\beta_j = \beta(\omega_j)$

PARAMETRIC ROLLING - EXIT TIME STRATEGY

exit time strategy:

- very long time domain simulation

$$(I + A)\ddot{\phi} + B(\dot{\phi})\dot{\phi} + C(t)\phi = 0 \quad C(t) = \bar{C} + \rho g V \partial GM(t)$$

- observe energy $E(\phi, \dot{\phi}) = \frac{1}{2}(I + A)\dot{\phi}^2 + \frac{1}{2}\bar{C}\phi^2$
- define critical amplitude and critical energy $E_{\text{crit}} = \frac{1}{2}\bar{C}\phi_{\text{crit}}^2$

PARAMETRIC ROLLING - EXIT TIME STRATEGY

Fraction of runs arriving within time T at E_{crit} : $q(T) = \min\left(\frac{T}{T_{int}}, 1\right)$

Weighted average over all safe zones: $\hat{q}(T)$

PARAMETRIC ROLLING - PROBABILITY

SHORT CRESTED WAVES

long crested waves
are 'easy':

- to analyse
- to simulate

however:
real waves are
short crested

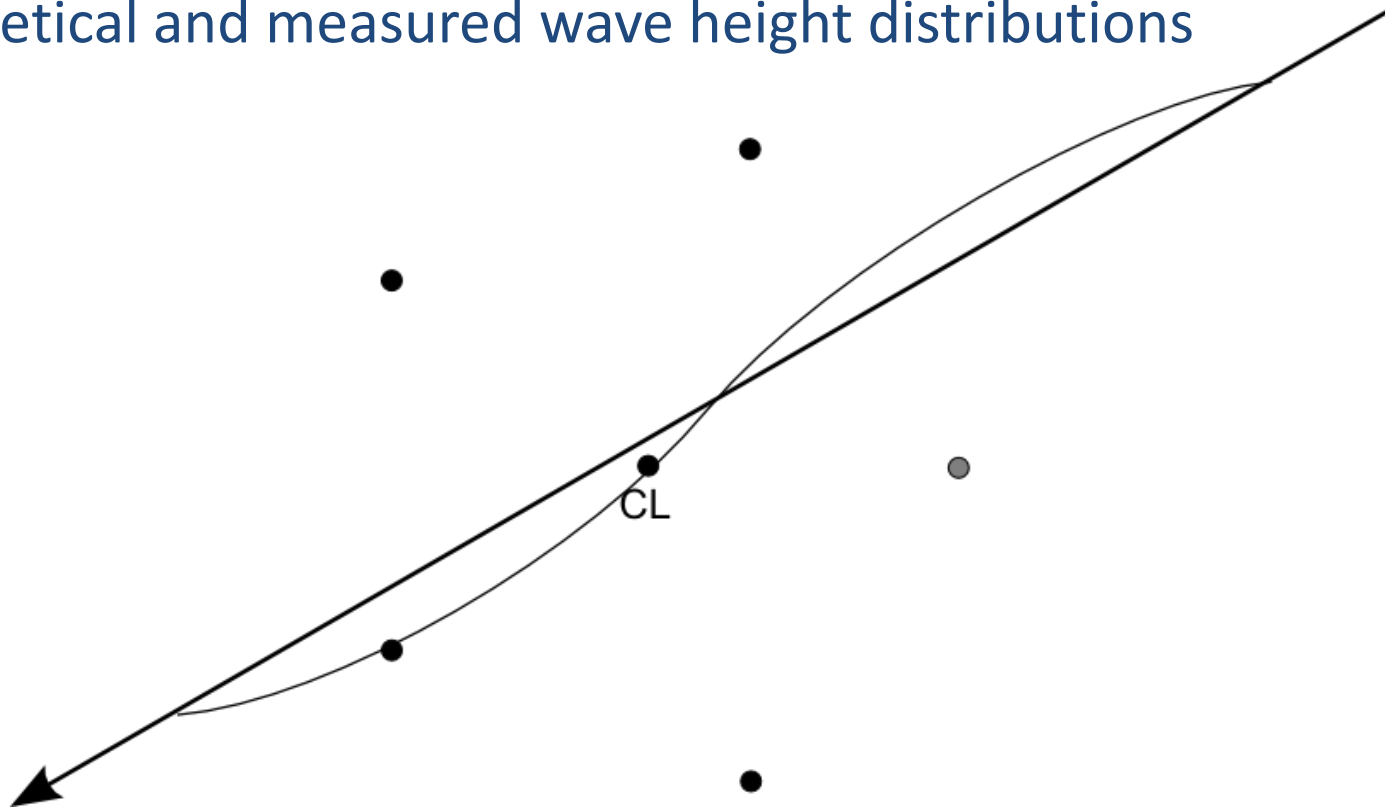

SHORT CRESTED WAVES

find wave spreading functions that match theoretical and measured wave height distributions

SHORT CRESTED WAVES

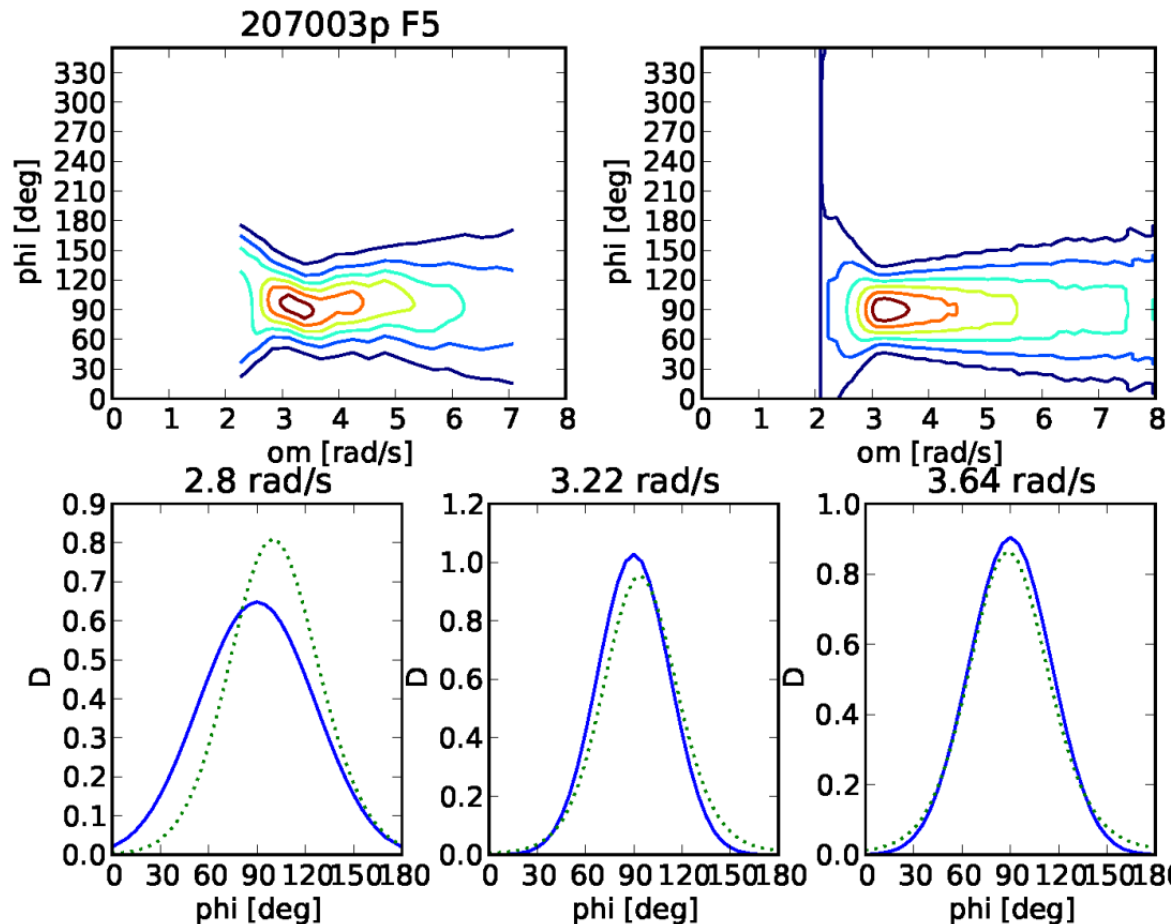

find wave spreading functions that match theoretical and measured wave height distributions

SHORT CRESTED WAVES

wave calibration using Maximum Likelihood Method

→ find wave spreading functions that match measured cross spectra with theoretical wave height transfer function

NUMERICAL DAMPING AND DISPERSION

NUMERICAL DAMPING AND DISPERSION

Consider plane surface waves on 2D uniform flow. Linearise in these waves. They are represented by Fourier components:

$$\bar{q} \equiv \begin{pmatrix} u \\ w \\ \psi \end{pmatrix} = \iint \begin{pmatrix} \hat{u} \\ \hat{w} \\ \hat{\psi} \end{pmatrix} e^{ikx+sz} dkds$$

Substitute this in the linearised and discretised RANS equations:

$$L_h \cdot \bar{q} = \iint \hat{L}_h(k, s) \cdot \hat{q} e^{ikx+sz} dkds = 0$$

L_h = RANS-operator, \hat{L}_h = discrete Fourier symbol of this operator

Non-trivial solution only exists if determinant of \hat{L}_h vanishes.

NUMERICAL DAMPING AND DISPERSION

- Continuous problem: wave number $k_0 = 1 / Fn^2$
- Discretised problem: wave number k , dependent on all difference schemes used.
- Damping and dispersion determined by k / k_0
- Dispersion determined by real part
- Damping determined by imaginary part

NUMERICAL DAMPING AND DISPERSION

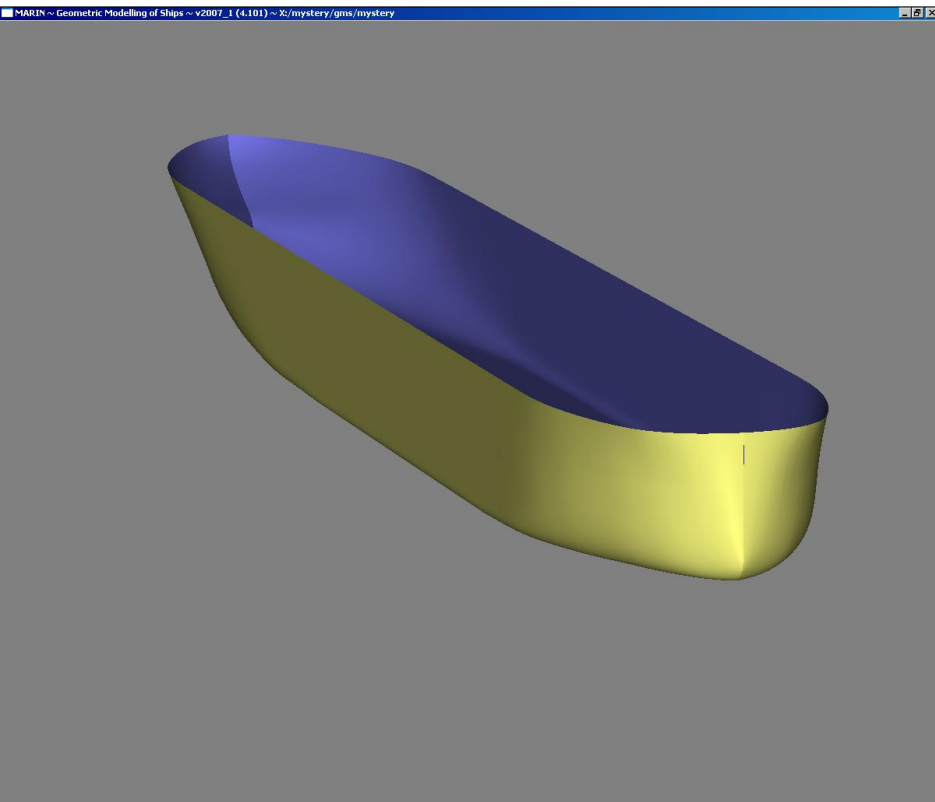

- Standard:
2nd-order dispersion,
3rd-order damping
- It is possible to design a dp/dx scheme for the FSBC that cancels leading-order error terms from other difference schemes: 'Balanced scheme':
3rd-order dispersion,
5th-order damping

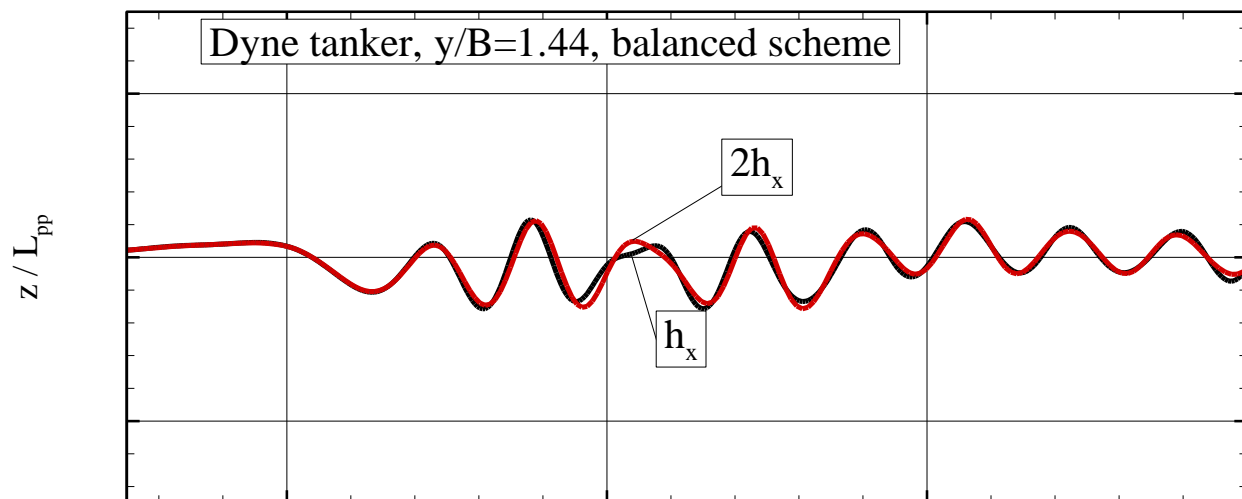

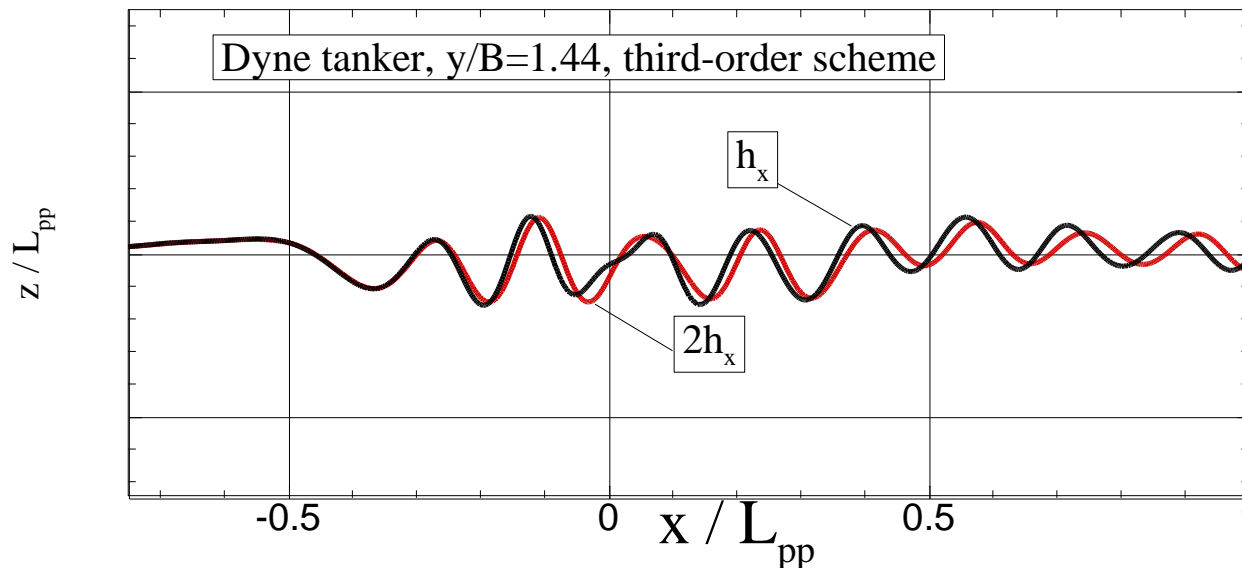

NUMERICAL DAMPING AND DISPERSION

Dyne tanker, $F_n=0.165$, $C_b=0.87$

model scale: $553 \times 121 \times 45 = 3.0\text{M}$ cells, full scale: $553 \times 161 \times 45 = 4.0\text{M}$ cells

NUMERICAL DAMPING AND DISPERSION

ANTI-ROLL TANKS

empty tank

filled tank

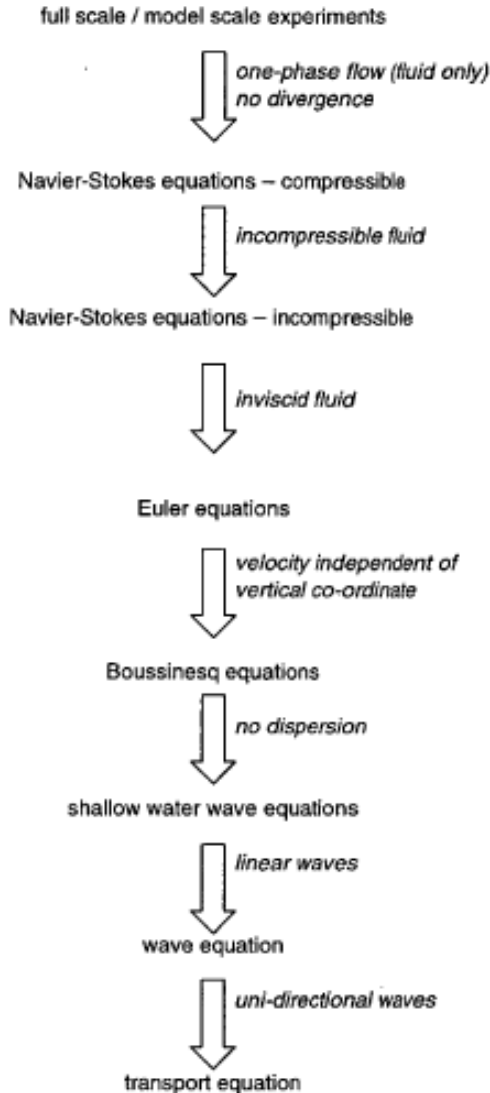

ANTI-ROLL TANKS – CFD U-TANK INTERNAL FLOW

ANTI-ROLL TANKS – VALIDATION OF CFD

ANTI-ROLL TANKS - COMPLEX OR SIMPLE APPROACH ?

complex geometries:
use CFD or experiments

simple geometries:
use analytical-empirical models

REDUCTION OF OFFSHORE BASIN EFFECTS

- rectangular basin (44.8m x36m), adjustable depth up to 10 m
- individually controlled wave flaps on 2 sides (112/90)
- beaches on opposite sides
- wind and current
- due to the finite dimension of the basin, long crested waves are not entirely long crested
- reflections due to presence of test models (ships/offshore platforms) may affect test results

REDUCTION OF OFFSHORE BASIN EFFECTS

linearized potential flow model

$$\Delta\phi = 0$$

$$\frac{\partial^2\phi}{\partial t^2} + g\frac{\partial\phi}{\partial z} = 0$$

$$\frac{\partial\phi}{\partial n} = \vec{V}\cdot\vec{n}$$

frequency domain

$$F(t) = \hat{F}e^{-i\omega t}$$

numerical solution:

boundary element (panel)

method with zero speed

Green functions $G(P,Q)$

$$\phi^j(P) = \int_S \sigma(Q)G(P,Q)dS$$

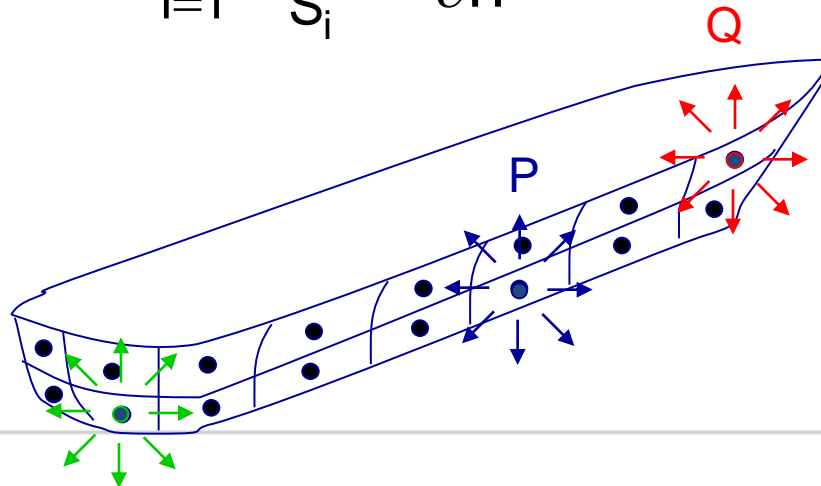

$$\frac{\partial\phi^j(P)}{\partial n} = 2\pi\sigma(P) + \int_S \sigma(Q)\frac{\partial G(P,Q)}{\partial n}dS$$

REDUCTION OF OFFSHORE BASIN EFFECTS

discretization: constant source per panel

$$\phi^j(P) = \sum_{i=1}^N \sigma_i \int_{S_i} G(P, Q) dS$$

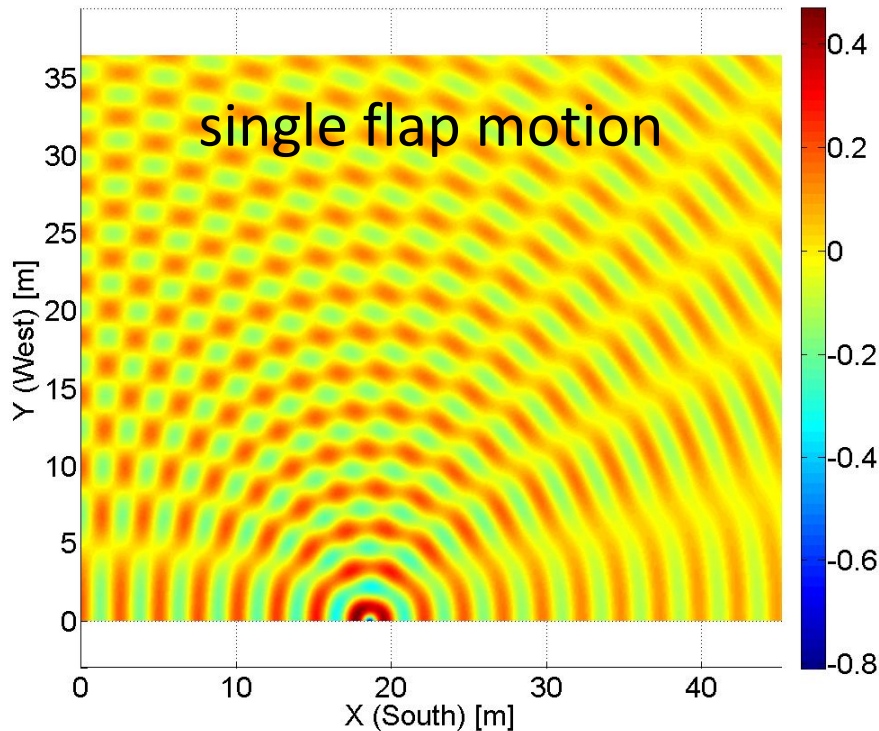

$$\frac{\partial \phi^j(P)}{\partial n} = 2\pi\sigma(P) + \sum_{i=1}^N \sigma_i \int_{S_i} \frac{\partial G(P, Q)}{\partial n} dS$$

REDUCTION OF OFFSHORE BASIN EFFECTS

use ship motion program to calculate basin waves (why not?)
waves generated by flaps
each flap is modeled as a separate moving body

wave snapshot [m/rad] due to flap unit rotation, $\omega = 4.9$ rad/s

linear superposition of waves

$$\eta_{tot}(x, y, \omega) = \sum_{k=1}^{N_{paddle}} A_k \eta_k(x, y, \omega)$$

beaches are modeled as
open boundaries (no
reflections)

REDUCTION OF OFFSHORE BASIN EFFECTS

waves generated by all flaps on south side moving identically

→ this is not long-crested !!!

wave snapshot [m/rad] due to flap unit rotation, $\omega = 4.9$ rad/s

wave RAO [m/rad] due to flap unit rotation, $\omega = 4.9$ rad/s

REDUCTION OF OFFSHORE BASIN EFFECTS

linear amplitude fade-out of outer 7 flaps
(default solution in basin wave control software)

wave snapshot due to flap unit rotation [m/rad], $\omega = 4.9$ rad/s, linear fade out 7 outer flaps

wave RAO due to flap unit rotation [m/rad], $\omega = 4.9$ rad/s, linear fade out 7 outer flaps

→ already much better !!!

REDUCTION OF OFFSHORE BASIN EFFECTS

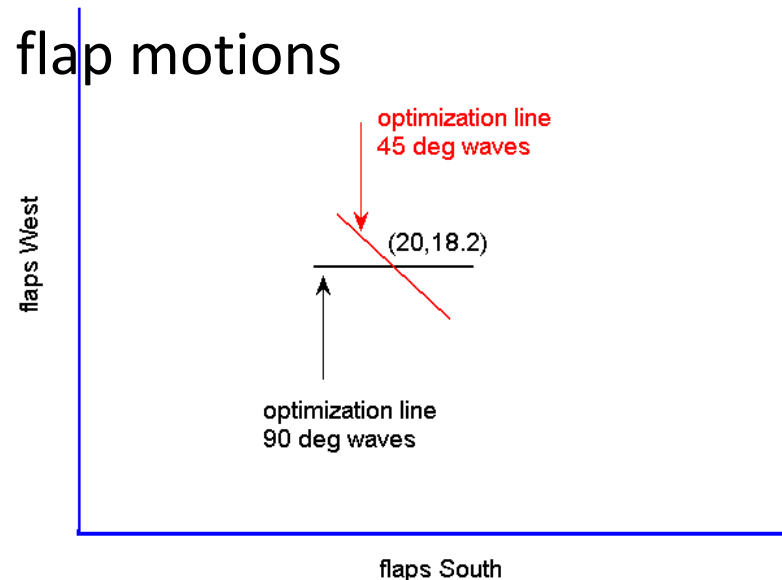

Can we do better than linear fade-out? Use optimization techniques!

Minimize the objective function $F(A_1 \dots A_M) = \sqrt{\sigma(\eta_{tot,r})^2 + \sigma(\eta_{tot,i})^2}$

$\eta_{tot,r}$ real part total wave elevation on optimization line

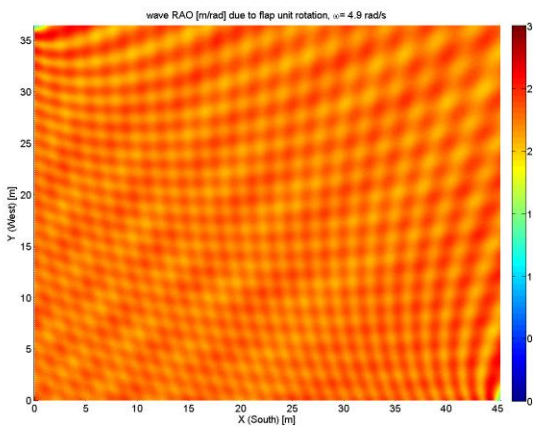

$\eta_{tot,i}$ imaginary part total wave elevation on optimization line

$A_1 \dots A_M$ complex amplitudes of M flap motions

REDUCTION OF OFFSHORE BASIN EFFECTS

45 degrees waves

CONCLUSIONS

- applied mathematics is *essential* for research on ship hydromechanics
- successful application of mathematics requires knowledge of mathematical solution techniques *and* understanding of physical / technical problems
- we need mathematicians that can think/talk/do (ship) hydromechanics *and* naval architects* that can think/talk/do (applied) mathematics, both at a sufficient level to 'reach out and touch'
- we need ability and courage to model:
 - reduce & assume
 - extrapolate & validate
 - think 'out of the box'

* and people from other disciplines, of course

THANK YOU FOR YOUR ATTENTION !

$$\min P(T_i, \alpha_i)$$

$$\sum_i \eta_i F_{x,i} = F_{x,\text{req}} \text{ etc.}$$

$$\underline{F} = \iint_S \underline{p} \underline{n} dS$$

www.marin.nl

$$\underline{\dot{U}} = \underline{F}(\underline{U}, \underline{\lambda}) = \underline{0}$$

$$\Delta\phi = 0$$
