June 8, 2018

4TU-AMI Symposium “Reducing dimensions in Big Data:  
Model Order Reduction in action”

# Data and Model Order Reduction

# Motivation/Outline

- ▶ **Motivation:** Randomized methods have got a steadily growing deal of attention in recent years, especially for problems in large-scale data analysis.

Two most important benefits:

- They can result in faster algorithms, either in worst-case asymptotic theory and/or numerical implementation,
  - they allow very often for (novel) tight error estimators
- ▶ **Topic of this talk:** Show how we can benefit from randomized methods in model order reduction

# Motivation/Outline

- ▶ **Motivation:** Randomized methods have got a steadily growing deal of attention in recent years, especially for problems in large-scale data analysis.

Two most important benefits:

- They can result in faster algorithms, either in worst-case asymptotic theory and/or numerical implementation,
  - they allow very often for (novel) tight error estimators
- ▶ **Topic of this talk:** Show how we can benefit from randomized methods in model order reduction
- ▶ **Outline:**
    - 1 Introduction to projection-based model order reduction
    - 2 Construct reduced spaces via randomized methods
    - 3 Randomized a posteriori error estimator for projection-based model reduction

# Parametrized Partial Differential Equation

- ▶ Parameter vector  $\mu \in \mathcal{P}$ ; compact parameter set  $\mathcal{P} \subset \mathbb{R}^P$
- ▶ **Parametrized PDE**: Given any  $\mu \in \mathcal{P}$ , find  $u(\mu) \in X$ , s.th.

$$A(\mu)u(\mu) = f(\mu) \quad \text{in } X'.$$

- ▶  $\Omega \subset \mathbb{R}^3$ : bounded domain with Lipschitz boundary  $\partial\Omega$
- ▶  $H_0^1(\Omega)^d \subset X \subset H^1(\Omega)^d$  ( $d = 1, 2, 3$ );  $X'$ : dual space
- ▶  $A(\mu) : X \rightarrow X'$ : **inf-sup stable, continuous linear differential operator**
- ▶  $f(\mu) : X \rightarrow \mathbb{R}$ : continuous linear form

# Parametrized Partial Differential Equation

- ▶ Parameter vector  $\mu \in \mathcal{P}$ ; compact parameter set  $\mathcal{P} \subset \mathbb{R}^P$
- ▶ **Parametrized PDE**: Given any  $\mu \in \mathcal{P}$ , find  $u(\mu) \in X$ , s.th.

$$A(\mu)u(\mu) = f(\mu) \quad \text{in } X'.$$

- ▶ **High-dimensional discretization**:
- ▶ Introduce high-dimensional FE space  $X^{\mathcal{N}} \subset X$  with  $\dim(X^{\mathcal{N}}) = \mathcal{N}$  (assume small discretization error)
- ▶ High-dimensional approximation: Given any  $\mu \in \mathcal{P}$ , find  $u^{\mathcal{N}}(\mu) \in X^{\mathcal{N}}$ , s.th.

$$A(\mu)u^{\mathcal{N}}(\mu) = f(\mu) \quad \text{in } X^{\mathcal{N}'}$$

- ▶ Issue: Require  $u^{\mathcal{N}}(\mu)$  in **real time** and/or for **many**  $\mu \in \mathcal{P}$ .

# Parametrized Partial Differential Equation

- ▶ Parameter vector  $\mu \in \mathcal{P}$ ; compact parameter set  $\mathcal{P} \subset \mathbb{R}^P$
- ▶ **Parametrized PDE**: Given any  $\mu \in \mathcal{P}$ , find  $u(\mu) \in X$ , s.th.

$$A(\mu)u(\mu) = f(\mu) \quad \text{in } X'.$$

- ▶ **High-dimensional discretization**:
- ▶ Introduce high-dimensional FE space  $X^{\mathcal{N}} \subset X$  with  $\dim(X^{\mathcal{N}}) = \mathcal{N}$  (assume small discretization error)
- ▶ High-dimensional approximation: Given any  $\mu \in \mathcal{P}$ , find  $u^{\mathcal{N}}(\mu) \in X^{\mathcal{N}}$ , s.th.

$$\underline{A}(\mu)\underline{u}^{\mathcal{N}}(\mu) = \underline{f}(\mu) \quad \underline{A}(\mu) \in \mathbb{R}^{\mathcal{N} \times \mathcal{N}}, \underline{f}(\mu) \in \mathbb{R}^{\mathcal{N}}.$$

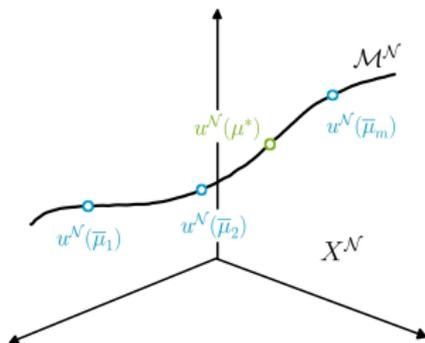

- ▶ Issue: Require  $u^{\mathcal{N}}(\mu)$  in **real time** and/or for **many  $\mu \in \mathcal{P}$** .

# Projection-based model order reduction: key concept

- ▶ Exploit:  $u^{\mathcal{N}}(\mu)$  belongs to “solution manifold”  $\mathcal{M}^{\mathcal{N}} = \{u^{\mathcal{N}}(\mu) \mid \mu \in \mathcal{P}\} \subset X^{\mathcal{N}}$  of typically very low dimension
- ▶ Offline: Construct reduced space  $X^N \subset X^{\mathcal{N}}$  from solutions  $u^{\mathcal{N}}(\bar{\mu}_i)$ ,  $i = 1, \dots, N$  (e.g. by a Greedy algorithm, Proper Orthogonal Decomposition,...)
- ▶ Online: Galerkin projection on  $X^N$ : Given any  $\mu^* \in \mathcal{P}$ , find  $u^N(\mu^*) \in X^N$ , s.th.

$$A(\mu^*)u^N(\mu^*) = f(\mu^*) \quad \text{in } X^N.$$

- ▶ If  $\mathcal{M}^{\mathcal{N}}$  is smooth,  $N \ll \mathcal{N}$  already yields a very accurate approximation. ([DeVore Petrova Wojtaszczyk 13])

For an overview on model order reduction see for instance [Benner, Cohen, Ohlberger, Willcox 2017].

# Proper Orthogonal Decomposition via SVD

- ▶ Introduce finite dimensional training set  $\mathcal{P}^{train} \subset \mathcal{P}$  of dimension  $n_{train}$
- ▶ Compute solutions  $\underline{u}^{\mathcal{N}}(\mu)$  for all  $\mu \in \mathcal{P}^{train}$
- ▶ Store coefficients in a so-called snapshot matrix:  
$$Y = [\underline{u}^{\mathcal{N}}(\mu_1) | \dots | \underline{u}^{\mathcal{N}}(\mu_{n_{train}})]$$
- ▶ Perform Singular Value decomposition:  $Y = U\Sigma V^*$
- ▶ Use first  $N$  left singular vectors to define reduced space

---

## Algorithm 1: Greedy algorithm

---

**input** : finite dimensional training set  $\mathcal{P}^{train} \subset \mathcal{P}$ , tolerance  $tol$

**output**:  $S_N, X^N$

**Initialize**:  $S_1 = \emptyset, X^0 = \{0\}, \Delta_0(\mu) = \|u^{\mathcal{N}}(\mu)\|_X$

**for**  $N = 1 : N_{max}$  **do**

Find:  $\mu_N = \arg \max_{\mu \in \mathcal{P}^{train}} \Delta_{N-1}(\mu). \quad (\|u^{\mathcal{N}}(\mu) - u^N(\mu)\|_X \leq \Delta_N(\mu))$

Solve for  $u^{\mathcal{N}}(\mu_N)$ .

Extend:  $S_N = S_{N-1} \cup \mu_N$  and  $X^N = \text{span}\{u^{\mathcal{N}}(\mu_1), \dots, u^{\mathcal{N}}(\mu_N)\}$ .

Compute  $\Delta_N(\mu)$  for all  $\mu \in \mathcal{P}^{train}$ .

**if**  $\arg \max_{\mu \in \mathcal{P}^{train}} \Delta_N(\mu) \leq tol$  **then**

| **break**

**end**

**end**

---

## Certification via a posteriori error bound

- ▶ A posteriori error estimator is important both
  - to construct reduced order models via the greedy
  - certify the approximation in the online stage: how large is the error (in some quantity of interest)?

### Proposition (A posteriori error bound)

The error estimator  $\Delta_N(\mu) = \beta_{LB}(\mu)^{-1} \|f(\mu) - A(\mu)u^N(\mu)\|_{X^N}$ , with  $\beta_{LB}(\mu) \leq \beta_N(\mu)$  satisfies

$$\|u^N(\mu) - u^N(\mu)\|_X \leq \Delta_N(\mu) \leq \frac{\gamma_N(\mu)}{\beta_{LB}(\mu)} \|u^N(\mu) - u^N(\mu)\|_X,$$

where  $\beta_N(\mu) := \inf_{v \in X^N} \sup_{w \in X^N} \frac{\langle A(\mu)v, w \rangle}{\|v\|_X \|w\|_X}$  and  $\gamma_N(\mu) = \sup_{v \in X^N} \sup_{w \in X^N} \frac{\langle A(\mu)v, w \rangle}{\|v\|_X \|w\|_X}$ .

- ▶ Problem: Good estimate of inf-sup often computationally infeasible  
→ constant-free randomized error estimators

# Constructing reduced order models via methods from randomized numerical linear algebra

For an overview on algorithms in randomized numerical linear algebra see for instance: [Halko et al 2011], [Mahoney 2011], [Drineas, Mahoney, 2016]

# Randomized SVD

- ▶ **Goal:** Given a snapshot matrix  $Y \in \mathbb{R}^{\mathcal{N} \times n_{train}}$  and an integer  $k$  find an orthonormal matrix  $Q$  of rank  $k$  such that  $Y \approx QQ^*Y$ .
- ▶ **Approach:**
  - ▶ Draw  $k$  random vectors  $r_j \in \mathbb{R}^{n_{train}}$  (say standard Gaussian)
  - ▶ Form sample vectors  $s_j = Yr_j \in \mathbb{R}^{\mathcal{N}}$   $j = 1, \dots, k$ .
  - ▶ Orthonormalize  $s_j \rightarrow q_j, j = 1, \dots, k$  and define  $Q = [q_1, \dots, q_k]$
  - ▶ **Result:** If  $Y$  has exactly rank  $k$  then  $q_j, j = 1, \dots, k$  span the range of  $Y$  at probability 1. But also in the general case  $q_j, j = 1, \dots, k$  often perform nearly as good as the  $k$  leading left singular vectors of  $Y$
- ▶ **Compute randomized SVD:**
  - ▶ Form  $C = Q^*Y$  which yields  $Y \approx QC$
  - ▶ Compute SVD of the small matrix  $C = \tilde{U}\Sigma V^*$  and set  $U = Q\tilde{U}$

# Reduced order modelling for large-scale problems

Limitations of standard model order reduction approach:

- ▶ **Curse of parameter dimensionality**: many parameters require prohibitively large reduced spaces
- ▶ **No topological flexibility** (although geometric variation is possible)
- ▶ Possibly **high computational costs** in the **offline stage**

→ **Localized model order reduction**

For each small subdomain  $\omega_i$  (e.g.  $\omega_{816}$ , **yellow**)  
we introduce an oversampling domain  $\omega_i^*$  (e.g.  $\omega_{816}^*$ , **green**)

# Constructing local reduced models via a transfer operator

Introduce **transfer operators**  $T_i$ :

- ▶ ... acts on the space of local solutions of the PDE and maps values  $\zeta$  on  $\partial\omega_i^*$  to  $\omega_i$
- ▶ ... by solving the PDE locally with Dirichlet boundary values  $\zeta$
- ▶ ... and restricting the local solution to  $\omega_i$

# Constructing optimal local spaces via transfer operators

- ▶ Key observation: Global solution  $u$  satisfies  $u|_{\omega_i} = T_i(u|_{\partial\omega_i^*})$

⇒ Construct local reduced spaces that approximate  $\text{range}(T_i)$

- ▶  $\phi_j$ : the left singular vectors of  $T_i$ ;  $\sigma_j$ : singular values of  $T_i$
- ▶ The reduced space

$$R_i^{\text{opt},n} := \text{span}\{\phi_1, \dots, \phi_n\}$$

is the **optimal space** and minimizes the approximation error among all spaces of the same dimension

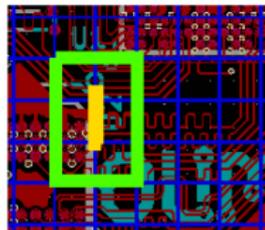

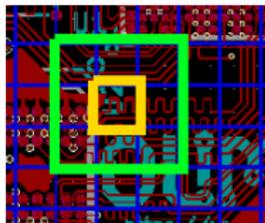

- ▶ The error satisfies:

$$\|T_i - P_{R_i^{\text{opt},n}} T_i\| = \sigma_{n+1}, \quad P_{R_i^{\text{opt},n}} : \text{orthogonal projection on } R_i^{\text{opt},n}$$

References: Babuska, Lipton, MMS, 2011; Smetana, Patera, SISC, 2016

## Approximating optimal local spaces with Randomized Linear Algebra

- ▶ Prescribe **random boundary conditions**; in detail choose every coefficient of a FEM basis function on  $\partial\omega_i^*$  as a (mutually independent) **Gaussian random variable with zero mean and variance one**
- ▶ **Solve PDE for random boundary conditions numerically** and store evaluation of local solution of PDE  $u|_{\omega_i}$ .
- ▶ Define reduced space  $R_{i,rand}^n$  as the span of  $n$  such evaluations  $u|_{\omega_i}$ .

References: Buhr, Smetana, SISC, 2018

## Approximating optimal local spaces with Randomized Linear Algebra

- ▶ **Solve PDE for random boundary conditions numerically** and store evaluation of local solution of PDE  $u|_{\omega_i}$ .
- ▶ Define reduced space  $R_{i,rand}^n$  as the span of  $n$  such evaluations  $u|_{\omega_i}$ .

Questions: What is the quality of such an approximation?  
(How) can we determine the dimension of the reduced space for a given tolerance?

References: Buhr, Smetana, SISC, 2018

# Probabilistic a priori error bound<sup>1</sup>

Proposition (A priori error bound (Buhr, Smetana 18))

$T : S \rightarrow R$  transfer operator as above,  $p$  oversampling parameter,  $n, p \geq 2$

$$\mathbb{E} \| T_i - P_{R_{i,rand}^{n+p}} T_i \| \leq \underbrace{\sqrt{\frac{\lambda_{\max}^{M_R} \lambda_{\max}^{M_S}}{\lambda_{\min}^{M_R} \lambda_{\min}^{M_S}} \left\{ \left( 1 + \frac{\sqrt{n}}{\sqrt{p-1}} \right) \sigma_{n+1} + \frac{e\sqrt{n+p}}{p} \left( \sum_{j>n} \sigma_j^2 \right)^{1/2} \right\}}}_{\sim c\sqrt{n}\sigma_{n+1}}$$

Optimal convergence rate achieved via SVD:

$$\| T_i - P_{R_i^{opt,n}} T_i \| = \sigma_{n+1}$$

<sup>1</sup>based on results in [Halko, Martinsson, Tropp 11]

## Probabilistic a posteriori error bound<sup>2</sup>

Proposition (Probabilistic a posteriori error bound (Buhr, Smetana 2018))

$\{\underline{r}^{(j)} : j = 1, 2, \dots, n_t\}$ : *standard Gaussian vectors*

$$\text{Define } \Delta(n_t, \delta_{\text{tf}}) := \frac{c_{\text{est}}(n_t, \delta_{\text{tf}})}{\sqrt{\lambda_{\min}^{M_S}}} \max_{j \in \{1, \dots, n_t\}} \left( \|T_i \underline{r}^{(j)} - P_{R_{i, \text{rand}}^n} T_i \underline{r}^{(j)}\| \right)$$

Then there holds

$$\|T_i - P_{R_{i, \text{rand}}^n} T_i\| \leq \Delta(n_t, \delta_{\text{tf}}) \leq \left( \frac{\lambda_{\max}^{M_S}}{\lambda_{\min}^{M_S}} \right)^{1/2} c_{\text{eff}}(n_t, \delta_{\text{tf}}) \|T_i - P_{R_{i, \text{rand}}^n} T_i\|$$

with a probability of at least  $1 - \delta_{\text{tf}}$ .

<sup>2</sup>Estimator extends results in [Halko, Martinsson, Tropp-11]; effectivity bound new

# Adaptive randomized range finder

- ▶ **Input:** Select tolerance  $tol$ , failure probability  $\delta_{algofail}$
- ▶ While  $\Delta(n_t, \delta_{tf}) > tol$ 
  - Generate random boundary values on  $\partial\omega_i^*$
  - Apply transfer operator  $T_i$  to random boundary conditions
  - Add new solution to  $R_{i,rand}^n$
  - Orthonormalize solutions
  - Update a posteriori error estimator
- ▶ **Output:**  $R_{i,rand}^n$  such that  $\|T_i - P_{R_{i,rand}^n} T_i\| \leq tol$  with probability at least  $1 - \delta_{algofail}$

## Numerical Experiments for analytic test problem

## Numerical Experiments: interfaces

- ▶ local (oversampling) domain  $\omega^* := (-1, 1) \times (0, 1)$
- ▶ Consider PDE:  $-\Delta u = 0$  in  $\omega^*$
- ▶ Goal: Construct reduced space on interface  $\Gamma_{in}$

Figure:  $\omega^*$

Heat conduction:  $-\Delta u = 0$  on  $\omega^* = (-1, 1) \times (0, 1)$

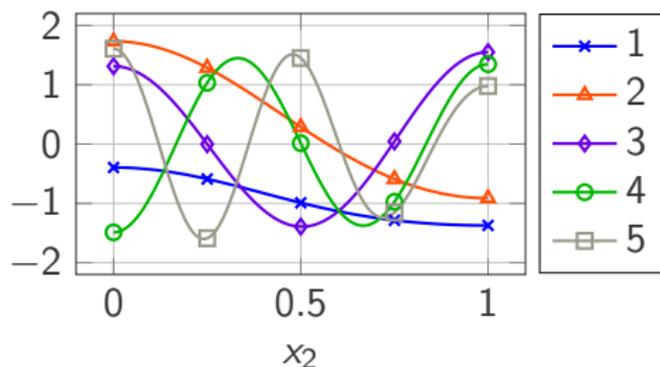

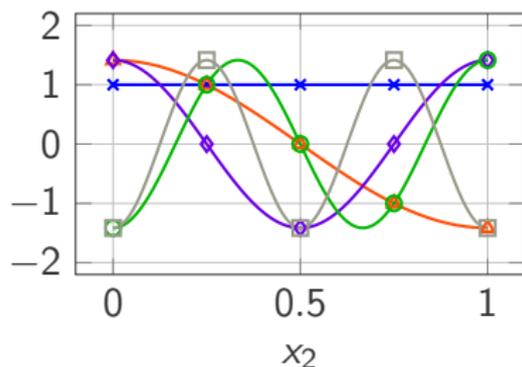

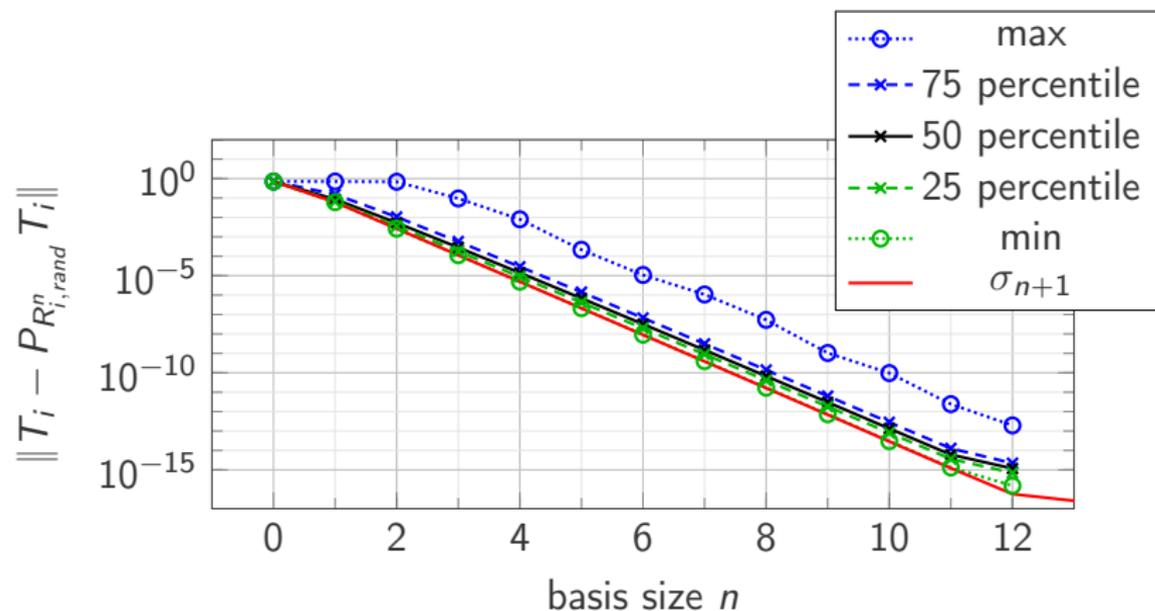

Figure: optimal basis

basis generated by randomized range finder algorithm

Heat conduction:  $-\Delta u = 0$  on  $\omega^* = (-1, 1) \times (0, 1)$

Heat conduction:  $-\Delta u = 0$  on  $\omega^* = (-1, 1) \times (0, 8)$

## CPU times

### *Properties of basis generation*

	randomized	Scipy/ARPACK
(resulting) basis size $n$	39	39
operator evaluations	59	79
adjoint operator evaluations	0	79
execution time in s (without factorization)	20.4 s	47.9 s

**Table:** CPU times; Target accuracy  $\text{tol} = 10^{-4}$ , number of testvectors  $n_t = 20$ , failure probability  $\delta_{\text{algofail}} = 10^{-15}$ ; unknowns of corresponding problem 638,799

# Numerical Experiments for a transfer operator with slowly decaying singular values

## Numerical Experiments: subdomains

- ▶ local (oversampling) domain  $\omega^* := (-2, 2) \times (-0.25, 0.25) \times (-2, 2)$
- ▶ Consider PDE: linear elasticity in  $\omega^*$  (isotropic, homogeneous)
- ▶ Goal: Construct reduced space on  $\omega = (-0.5, 0.5) \times (-0.25, 0.25) \times (-0.5, 0.5)$

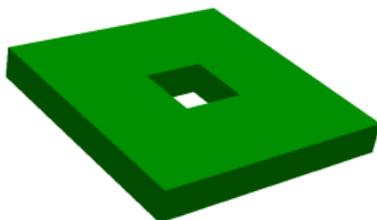

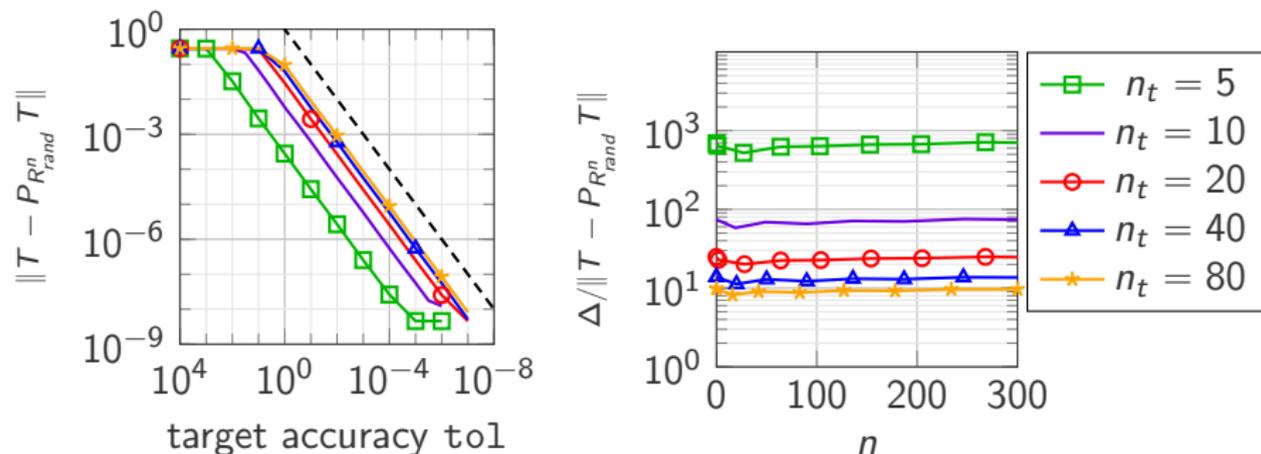

Figure:  $\omega^* \setminus \omega$

Linear elasticity on  $\Omega := (-2, 2) \times (-0.5, 0.5) \times (-2, 2)$ 

**Figure:** Convergence behavior of adaptive algorithm (left) and effectivity of a posteriori error estimator  $\Delta / \|T - P_{rand}^n T\|$  (right) for increasing number of test vectors  $n_t$ .

- ▶ Zahm, Nouy 2016
- ▶ Giraldi, Nouy 2017
- ▶ Balabanov, Nouy 2018

- ▶ **Goal:** Develop a posteriori error estimator for projection-based model order reduction that does not contain constants whose estimation is expensive (inf-sup constant)
- ▶ **Setting:** We query a finite number of parameters in the online stage for which we want to estimate the approximation error.
- ▶ **Approach:** Exploit concentration inequalities:

### Proposition (Concentration inequality, Johnson-Lindenstrauss)

*Choose rows of matrix  $\Phi \in \mathbb{R}^{K \times \mathcal{N}}$  say as  $K$  independent copies of standard Gaussian random vectors scaled by  $1/\sqrt{K}$  and let  $\mathcal{S} \subset \mathbb{R}^{\mathcal{N}}$  be a finite set. Moreover, assume  $K \geq (C(z)/\varepsilon^2) \log(\#\mathcal{S}/\delta)$ . Then we have*

$$\mathbb{P} \left\{ (1 - \varepsilon) \|x - y\|_2^2 \leq \|\Phi x - \Phi y\|_2^2 \leq (1 + \varepsilon) \|x - y\|_2^2 \quad \forall x, y \in \mathcal{S} \right\} \geq 1 - \delta.$$

see for instance [Boucheron, Lugosi, Massart 2012], [Vershynin 2012], [Vershynin 2018]

## Assumptions on random vector

- ▶  $Z \in \mathbb{R}^{\mathcal{N}}$ : random vector such that

$$\|v\|_{\Sigma}^2 = v^T \Sigma v = \mathbb{E}((Z^T v)^2) \quad \forall v \in \mathbb{R}^{\mathcal{N}},$$

where  $\Sigma$  is matrix e.g. associated with  $H^1$ - or  $L^2$ -inner product or a quantity of interest

$\implies (Z^T v)^2$  is an unbiased estimator of  $\|v\|_{\Sigma}^2$

# Assumptions on random vector

- ▶  $Z \in \mathbb{R}^{\mathcal{N}}$ : random vector such that

$$\|v\|_{\Sigma}^2 = v^T \Sigma v = \mathbb{E}((Z^T v)^2) \quad \forall v \in \mathbb{R}^{\mathcal{N}},$$

where  $\Sigma$  is matrix e.g. associated with  $H^1$ - or  $L^2$ -inner product or a quantity of interest

⇒  $(Z^T v)^2$  is an unbiased estimator of  $\|v\|_{\Sigma}^2$

- ▶ For simplicity: Assume  $Z \sim \mathcal{N}(0, \Sigma)$  is a Gaussian vector with zero mean and covariance matrix  $\Sigma$

## Assumptions on random vector

- ▶  $Z \in \mathbb{R}^{\mathcal{N}}$ : random vector such that

$$\|v\|_{\Sigma}^2 = v^T \Sigma v = \mathbb{E}((Z^T v)^2) \quad \forall v \in \mathbb{R}^{\mathcal{N}},$$

where  $\Sigma$  is matrix e.g. associated with  $H^1$ - or  $L^2$ -inner product or a quantity of interest

⇒  $(Z^T v)^2$  is an unbiased estimator of  $\|v\|_{\Sigma}^2$

- ▶ For simplicity: Assume  $Z \sim \mathcal{N}(0, \Sigma)$  is a Gaussian vector with zero mean and covariance matrix  $\Sigma$
- ▶  $Z_1, \dots, Z_K$ :  $K$  independent copies of  $Z$
- ▶ Consider the following (unbiased) Monte-Carlo estimator of  $\|v\|_{\Sigma}^2$

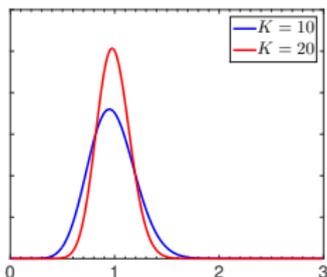

$$\frac{1}{K} \sum_{i=1}^K (Z_i^T v)^2.$$

## Proposition (Concentration inequality for set of vectors)

Given a *finite set of parameters*  $\mathcal{S} = \{\mu_1, \dots, \mu_S\} \subset \mathcal{P}$ , a failure probability  $0 < \delta < 1$ ,  $w \in \mathbb{R}$ ,  $w > \sqrt{e}$ , we have for  $\underline{e}(\mu_j) = \underline{u}^N(\mu_j) - \underline{u}^N(\mu_j)$ ,

$$K \geq \frac{\log(\#\mathcal{S}) + \log(\delta^{-1})}{\log(w/\sqrt{e})} \quad \text{that}$$

$$\mathbb{P} \left\{ \frac{\|\underline{e}(\mu_j)\|_{\Sigma}^2}{w^2} \leq \frac{1}{K} \sum_{i=1}^K (Z_i^T \underline{e}(\mu_j))^2 \leq w^2 \|\underline{e}(\mu_j)\|_{\Sigma}^2, \quad \forall \mu_j \in \mathcal{S} \right\} \geq 1 - \delta.$$

- ▶ chi-squared distribution
- ▶ concentration around 1 (that means error estimator has perfect effectivity 1)

## Proposition (Concentration inequality for set of vectors)

Given a *finite set of parameters*  $\mathcal{S} = \{\mu_1, \dots, \mu_S\} \subset \mathcal{P}$ , a failure probability  $0 < \delta < 1$ ,  $w \in \mathbb{R}$ ,  $w > \sqrt{e}$ , we have for  $\underline{e}(\mu_j) = \underline{u}^{\mathcal{N}}(\mu_j) - \underline{u}^{\mathcal{N}}(\mu_j)$ ,

$$K \geq \frac{\log(\#\mathcal{S}) + \log(\delta^{-1})}{\log(w/\sqrt{e})} \quad \text{that}$$

$$\mathbb{P} \left\{ \frac{\|\underline{e}(\mu_j)\|_{\Sigma}^2}{w^2} \leq \frac{1}{K} \sum_{i=1}^K (Z_i^T \underline{e}(\mu_j))^2 \leq w^2 \|\underline{e}(\mu_j)\|_{\Sigma}^2, \quad \forall \mu_j \in \mathcal{S} \right\} \geq 1 - \delta.$$

	$w = 2$	$w = 3$	$w = 4$	$w = 5$	$w = 10$
$\#\mathcal{S} = 1$	24	8	6	5	3
$\#\mathcal{S} = 100$	48	16	11	9	6
$\#\mathcal{S} = 1000$	60	20	13	11	7
$\#\mathcal{S} = 10^6$	96	31	21	17	11

**Table:** Values for  $K$  that guarantee (1) for all  $\mu_j \in \mathcal{S}$  with  $\delta = 10^{-2}$ .

## Proposition (Concentration inequality for set of vectors)

Given a *finite set of parameters*  $\mathcal{S} = \{\mu_1, \dots, \mu_S\} \subset \mathcal{P}$ , a failure probability  $0 < \delta < 1$ ,  $w \in \mathbb{R}$ ,  $w > \sqrt{e}$ , we have for  $\underline{e}(\mu_j) = \underline{u}^{\mathcal{N}}(\mu_j) - \underline{u}^{\mathcal{N}}(\mu_j)$ ,

$$K \geq \frac{\log(\#\mathcal{S}) + \log(\delta^{-1})}{\log(w/\sqrt{e})} \quad \text{that}$$

$$\mathbb{P} \left\{ \frac{\|\underline{e}(\mu_j)\|_{\Sigma}^2}{w^2} \leq \frac{1}{K} \sum_{i=1}^K (Z_i^T \underline{e}(\mu_j))^2 \leq w^2 \|\underline{e}(\mu_j)\|_{\Sigma}^2, \quad \forall \mu_j \in \mathcal{S} \right\} \geq 1 - \delta.$$

$$\text{Define } \Delta(\mu) := \left( \frac{1}{K} \sum_{i=1}^K (Z_i^T \underline{e}(\mu))^2 \right)^{1/2}$$

Problem: estimator  $\Delta(\mu) = \left( \frac{1}{K} \sum_{i=1}^K (Z_i^T (\underline{u}^{\mathcal{N}}(\mu_j) - \underline{u}^{\mathcal{N}}(\mu_j)))^2 \right)^{1/2}$

involves high-dimensional finite element solution

$\implies$  Computationally infeasible in the online stage

# A fast-to-evaluate randomized error estimator

- ▶ Exploit **error residual relationship**

$$Z_i^T \underline{e}(\mu) = Z_i^T \underline{A}(\mu)^{-1} \underbrace{(\underline{f}(\mu) - \underline{A}(\mu) \underline{u}^N(\mu))}_{\text{residual } \underline{r}(\mu) :=} = \underbrace{(\underline{A}(\mu)^{-T} Z_i)^T}_{\text{dual problem}} \underline{r}(\mu)$$

- ▶ Define solutions of **dual problems with random right-hand sides**  $Z_i$ :

$$\underline{y}_i^{\mathcal{N}}(\mu) := \underline{A}(\mu)^{-T} Z_i$$

- ▶ **Approximation of the dual solutions** via model order reduction:

$$\underline{y}_i^{\mathcal{N}}(\mu) \approx \tilde{\underline{y}}_i(\mu) \in \tilde{\mathcal{Y}} \subset \mathcal{X}^{\mathcal{N}},$$

where  $\tilde{\mathcal{Y}}$  dual reduced space

- ▶ Define **fast-to-evaluate randomized error estimator**

$$\tilde{\Delta}(\mu) := \left( \frac{1}{K} \sum_{i=1}^K (\tilde{\underline{y}}_i(\mu)^T \underline{r}(\mu))^2 \right)^{1/2}$$

# A fast-to-evaluate randomized error estimator

## Proposition

Choose  $S \in \mathbb{N}$  in the *offline stage*. Then, in the *online stage* for any given  $w > \sqrt{e}$  and  $\delta > 0$  we have for  $S$  different parameters values  $\mu_j, j = 1, \dots, S$  in a finite parameter set  $\mathcal{S} = \{\mu_1, \dots, \mu_S\}$  and

$$K \geq \frac{\log(S) + \log(\delta^{-1})}{\log(w/\sqrt{e})} \quad \text{that} \quad \tilde{\Delta}(\mu_j) := \left( \frac{1}{K} \sum_{i=1}^K (\tilde{y}_i(\mu_j)^T \underline{r}(\mu_j))^2 \right)^{1/2}$$

satisfies

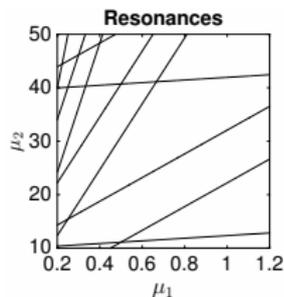

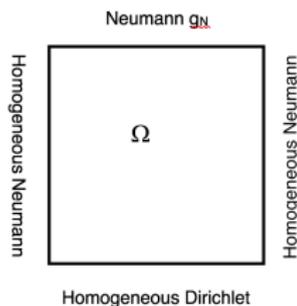

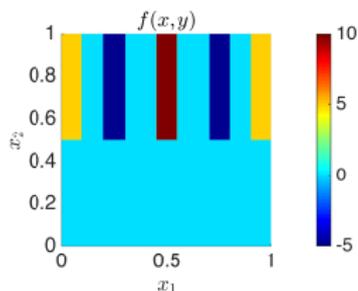

$$\mathbb{P} \left\{ (\alpha w)^{-1} \tilde{\Delta}(\mu_j) \leq \|\underline{e}(\mu_j)\|_{\Sigma} \leq (\alpha w) \tilde{\Delta}(\mu_j), \quad \mu_j \in \mathcal{S}, \right\} \geq 1 - \delta,$$

where

$$\alpha = \max_{\mu \in \mathcal{P}} \left( \max \left\{ \frac{\Delta(\mu)}{\tilde{\Delta}(\mu)}, \frac{\tilde{\Delta}(\mu)}{\Delta(\mu)} \right\} \right) \geq 1.$$

# Numerical experiments: acoustics in 2D

- ▶  $\Omega = (0, 1) \times (0, 1)$
- ▶  $X = \{v \in H^1(\Omega) : v(0, x_2) = 0, x_2 \in (0, 1)\}$
- ▶  $A(\mu) := -\partial_{x_1 x_1} - \mu_1 \partial_{x_2 x_2} - \mu_2$ ,
- ▶  $\mathcal{P} = [0.2, 1.2] \times [10, 50]$
- ▶ Neumann b.c. on top:  $g_N = \cos(\pi x)$

- ▶ high dimensional discretization: linear FE,  $h = 0.01$  in each direction

# Histograms of effectivity index $\tilde{\Delta}(\mu)/\|u(\mu) - u^N(\mu)\|_{H^1(\Omega)}$

5 realizations

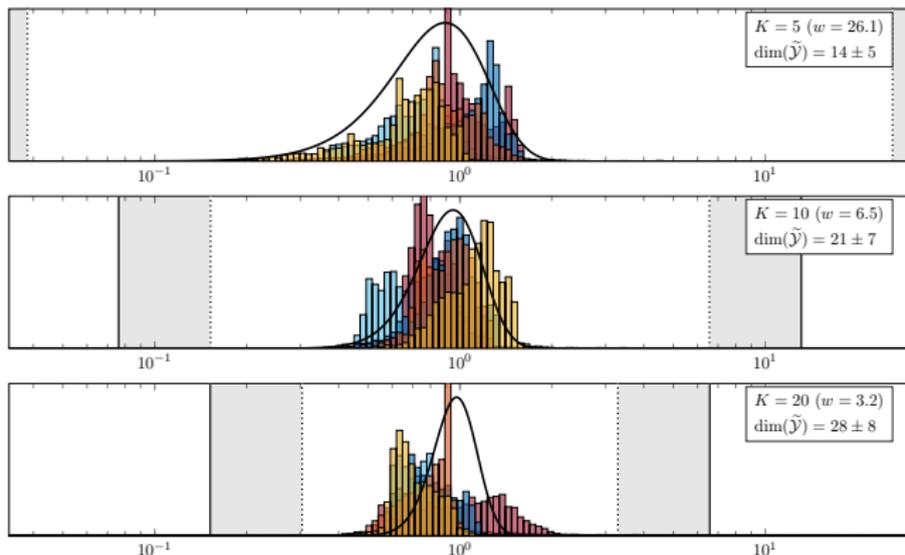

Figure:  $\#\mathcal{S} = 10^4$ ,  $\dim(X^N) = 20$ , vertical dashed lines:  $1/w$  and  $w$ , grey area:  $1/(tol \cdot w)$  and  $tol \cdot w$ , where  $\alpha \approx tol$ ,  $tol = 2$ , solid lines: chi-squared distribution

Histograms of effectivity index  $\tilde{\Delta}(\mu)/\|u(\mu) - u^N(\mu)\|_{H^1(\Omega)}$ 

100 realizations

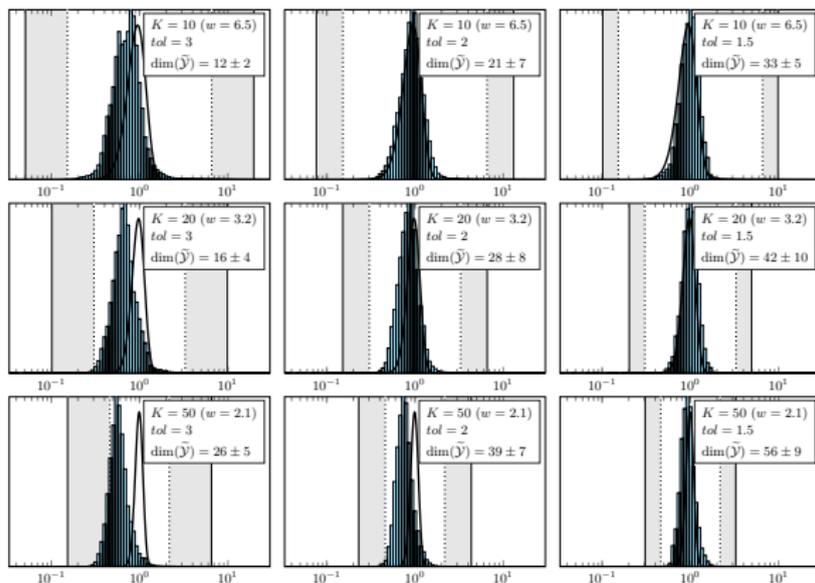

Figure:  $\#\mathcal{S} = 10^4$ ,  $\dim(X^N) = 20$ , vertical dashed lines:  $1/w$  and  $w$ , grey area:  $1/(tol w)$  and  $tol w$ , where  $\alpha \approx tol$ ,  $tol = 2$ , solid lines: chi-squared distribution

# Summary

- ▶ Reduced (local approximation) spaces generated by methods from Randomized Linear Algebra
  - Probabilistic a priori error bound/Numerical experiments: **convergence rate is only slightly worse compared to the optimal rate (factor  $\sqrt{n}$ )**.
  - Probabilistic a posteriori error bound allows to build the reduced space adaptively
  - **required number of local solutions of PDE scale (roughly) with size of the reduced space**; Numerical experiments: faster than Lanczos
- ▶ Proposed **randomized a posteriori error estimator** for projection-based model order reduction methods that...
  - ... is based on **concentration inequalities**, error-residual relationship, and **random dual problem**
  - ... **does only contain computable constants**
  - ... is reliable and efficient at high (given) probability
  - ... has a **favorable computational complexity** as  $\dim(\tilde{\mathcal{Y}})$  can be chosen relatively small
